INDEX OF CONTENTS.

JANUARY TO JUNE, 1888.

A

ANELIA floribunda, 728
 Aberdeen Agricultural Research Association, 558; Royal Horticultural Society of, 274, 371
Abies amabilis, 658; *A. magnifica*, 772; *A. nobilis*, 772; at Thorpe Perrow, 236; *A. numidica*, 140; *A. subalpina*, 586
Abutilons, 622
Acacia armata, 174, 373; *A. dealbata*, 339; *A. lophantha*, 339
Acacias, 265
Acer Schwedleri, 659
Achimenes, 267, 392
 Acton, recreation-ground at, 464
Adansonia Gregorii, 521
Adiantum Capillus-veneris var. *imbricata*, 72; *A. Fergusoni*, 497
Adonis pyrenaica, 715; *A. vernalis*, 689
Aeranthus grandiflora, 12
Aërides, cultivation of, 683; *A. Fieldingii*, 293
 African (South) plants, 727
Aganisia cyanea, 44
Agaricus melleus, 137
Agave americana aureo-variegata, 174
 Agriculture, a board of, 241
 Agricultural College, Downton, 530; Iowa, 772; Michigan, 50; Institute, Weald of Kent, 426
 Agricultural produce statistics, 338
 Algiers, 193
Allamandas drying off, 244, 277, 310, 404; winter treatment of, 437
Aloysia citriodora, 559
Aloe Hildebrandtii, 242
Alpinia officinarum, 149
 Alpine garden, 308, 554, 650, 715, 748
 Alpine plants, popularity of, 727
 Alpines at Kew, show-house for, 177
Alyssum pyrenaicum, 554
Amaraboya splendida, 242
Amaranthus salicifolius var., 204
 Ammanford garden, 596
Amaryllis, the, 56
Amaryllis and *Cliveas*, 522
Amaryllis as winter bloomers, 467; at Messrs. Veitch's, 467; cultivation of, 118; raising new varieties of, 107
Amaryllidaceæ, Handbook of, 771
 American notes, 116; Florists, Society of, 305
Amorphophallus virosus, 242
Andromeda (see *Zenobia*)
Anemone, the, 747; St. Brigid, 404
Anemones, St. Brigid, at home, 716; spring, 650
 Anglo-Danish Exhibition, 466
Angræcum ciliatum, 237; *A. dependens*, 237; *A. modestum*, 428; *A. Sanderianum*, 395
Angræcum at Clapton Nurseries, 75
 Annuals, 771

Antholysa bicolor, 299
Anthurium Chamberlaini, 462
 Ants and plants, 278
 Apiary, 302, 366, 531, 595, 653, 718, 802
 Apple culture, 492; in Cornwall, 586
 Apples and Pears, late British, 243
 Apples for cold soils, 718; from the Cape, 497; keeping, 24; a plague of caterpillars on, 789; to plant in New Zealand, 119
 Aquatic plants, 527
Aralia japonica, 180, 244
Aralias, 204, 244
Araucaria Bidwillii, 370; *A. brasiliensis*, 774; *A. Cookii*, 774; *A. Cunninghamii* glauca, 684; *A. excelsa*, 648; *A. imbricata*, 85
Araucarias at Dropmore, 691; of New Guinea, 82, 774
Ardisia crenulata, 174
Aristea Eckloni, 557
Aristolochia racemosa, 722
Aristolochia Westlandii, 332
Aristolochias, 777
 Arnold-arboretum, 435
Asparagus plumosus, 22
Aspleniums, 299
Aucuba cuttings, striking, 470
Aucuba in berry, 341
Auricula, the, 490
Auriculas, 430, 681; out-of-doors, 84; alpine, 620
Azalea Deutsche Perle, 434; *A. obtusa*, 435

B

Backhouse's nursery, York, 244, 554
 Balcony gardening, 682
 Balsams, 494
 Ballet, M., 83
Bambusa Veitchii, 332
 Banana trade, Trinidad, 14
 Bananas in Central America, 722
 Baobab tree, the, 494; the Australian, 521
 Barcelona, vegetable products in, 725
 Basic cinder, 310
 Bean and Pea beetle, 402
 Bean Ne Plus Ultra, 179
 Beans, fertilisation of, 694, 755, 781
Beanmontia grandiflora, 266, 469
 Bedding out, 86
 Bee flowers, 341; plants for large bee farms, 86
 Bees, 499
Begonia, hybrid, 779
Begonia Lubbersii, 300, 341, 492; and *B. argyrostigma*, 372
Begonia Rex, 269
Begonias as bedding plants in Scotland, 393; tuberosus in pots, 491; in Scotland, 469; winter flowering, 235
 Belgian nurseries, 524, 552, 587, 618, 651

Berberis chinensis, 278
 Berlin, 237; a new park for, 177; L. Späth's nursery, 266; flower market, 429; forced flowers in, 178.
 Berry-bearing plants, 19; shrubs, 115.
 Biarritz, 311
Bilbergia decora, 266
Biota Sieboldi, 205
 Birmingham Gardeners' Improvement Association, 306
Bletia hyacinthina, 746
 Boiler, a new (Brasseur's), 561, 596, 772
Boldoa fragrans, 14

Books:—Allotments (Rev. W. Tuckwell), 307; American Gardeners' Monthly, 148; Annals of Botany (Balfour), 467, 600; Art of Preparing Vegetables for the Table (Sutton), 618; Book of Domestic Poultry, 338; Botanical Magazine, 81, 82, 242, 305, 466, 592, 722; Botanical Works of Engelmann, 804; British Uredineæ and Ustilagineæ (Plowright), 370; Cassell's Popular Gardening, 42, 146; Chrysanthemum Annual (L. Castle), 402; Development of Tubers (H. Vöchting), 71; Familiar Trees, 779; Farmers' Friends and Foes (T. Wood), 363; Fifty Years of Economic Botany (J. W. Ellis), 797; Flora of the Hawaiian Islands (W. Hillebrand), 652; Flora of West Yorkshire (F. A. Lees), 434; Flore Forestière de la Cochinchine (Pierre), 689; Flowerland (Rev. R. Fisher), 338; Garden and Forest, 50, 338; Gardeners' Receipt Book (Joseph), 724; Gartenkunst und Garten Sonst und Jetzt (Jäger), 178; Handbook of Amaryllidaceæ (Baker), 724, 771; Hardy Flowers (W. Robinson), 19; How and What to Grow in a Kitchen Garden of One Acre (E. D. Darlington and L. M. Moll), 363; Icones Plantarum (Hooker), 369; Illustrations Floræ Insularum Maris Pacifici (Castello), 594; Journal of the Bath and West of England Society, 723; Kew Bulletin, 144, 178, 338, 539; Lindenia, 501; Malesia, 370; Manual of Orchidaceous Plants (Veitch & Sons), Part iii., 753; Obstbau, 402; Orticoltura, 178; Pansy, Cultivation of the (Lester), 657; Pflanzenphysiologie Practicum (W. Dettmer), 12; Pflanzenleben (Körner von Marilaun), 467; Plantæ Davidiana, 395; Plantkundig Woordenboek voor Nederlandisch-Indie (G. J. Fiset), 433; Reichenbachia, 689; Rosarian's Year-book, 144; Serres Vergers, les (Pynaert), 275; Vegetarian, 116
 Books, select list of for gardeners, 10

Borer of Apple trees, to keep out, 114
Boronia megastigma, 174
 Botanic Gardens, Calcutta, 205; Cambridge, 177; Cape Town, 599; Dublin, 177; Halle University, 625; Indian, 551; King William's Town, 775; Natal, 599; Padua, 116; Teneriffe, 711; Old Bedford, 744
 Botanical drying paper, 779; Record Club, 146; Society of Italy, 178
 Botany, the "Smart" studentship, 338; economic, 597
Bougainvillea spectabilis, 652
 Bouquet, a monster, 465
Bonvardias, 269
Brassavola cucullata var. *cuspidata*, 44
 Brazil-nut, germination of the, 18
 Broccoli, 729; Hanan's Late Protecting White, 776; Methven's Edinburgh Late, 776
Brownea grandiceps, 219; macrophylla, 523
Brugmansia culture, 34; *B. lutea*, 404; *B. l. fruiting*, 268; *B. suaveolens*, 340
Brugmansias, 23; planted out in a cool house, 173
 Brussels Exhibition, 241, 530
 Bulb garden, 83, 107, 171, 234, 207, 457, 524, 594, 621, 651, 683, 776
 Bulb-gardens at Haarlem, 685
 Bulbs at Natal, 621
 Bulbs at Natal, 775
 Bulbs and Caeti, Cape, 141
 Bulbs, Dutch, novelties in, 491
 Bullfinches and fruit buds, 244
 Burnt earth for plants, 806
 Burrs and Knaurs, 560, 744
 Buxley, Burton-on-Trent, glasshouses at, 691

C

Cannage, the Shantung, 619
 Caeti and bulbs, Cape, 141
 Caladiums, 269
Calanthe striata, 364; *C. Veitchii*, unusual growth of, 395
Calanthes, propagation of, 396
 Calceolaria, pouch of the, 684
 Calcutta Botanic Gardens, 205, 206
 Calcutta, Horticulture in, 497
 Calliandras, 266
Camellias, 83; at Walton Lea, Warrington, 562; new, 690
Campauala Allioni, 748
 Campion, double white, 425
 Canker in trees, experiments in curing, 752
 Cape and Natal plants, a comparison between, 649
 Capsicum, 116
 Caraboo fruits and Varach seeds, 238
 Carnation and Picotee, 110, 685
 Carnation and Picotee Union, the, 113
 Carnation buds, blind, 436; disease, 151

- Carnations, 22; border, 181; winter flowering, 174, 728; yellow, 620
 Carpeting under the Beech, 728
 Carpets of Pine wool, 171
 Catalogues illustrating, 276
Catatum Bungeothii var. *aureum*, 11; *C. pulchrum*, 235
Cattleya bicolor, 395; *C. Eldorado splendens*, 173; fertilisation of, 208; *C. labiata* var. *autumnalis*, 12; *C. l.* var. *Trianae* var. *Ernesti*, 203; *C. Lawrenceana*, 298, 619; *Cattleya*, regular pleoria of, 657; *C. velutina* var. *Lietzei*, 235; *C. Walkeriana*, 268
 Cauliflowers from Finisterre, 722
 Celeriac, 243
Caryota sobolifera, 334
 Cedars, chaining up, 807
Celosia pyramidalis var. 494
 Ceylon, 397
 Chalk, trees for, 398
 Charenton, a stream at, 428
 Chestnut disease, 805
 Chick-houses, 18
Chionodoxa Luciliae alba, 631
Chironia peduncularis, 800
 Chiswick Gardeners' Mutual Improvement Association, 177
 Chiswick, fruit and flowers at, 804; Pansies at, 776
 Chlorophyll in the epidermis, 177
 Christmas Rose culture, 396, 490
 Chrysanthemum, the, 174; *C. Golden Gem*, 84; *C. Guerusey Hero*, 178; judges, 85, 119, 152, 181
 Chrysanthemums, 436; best six Japanese for exhibition, 151; exhibitions of, 43; groups of, for competition, 532, 564; new departure in, 372; on walls, 373, 499; reflexed Japanese, 497
 Cineraria, 174, 469, 654; *C. Emperor Frederick* (Alexander Warwick), 436
Cinchona in Java, 806
 Cinerarias, 494, 497; double, 659
Cirrhopetalum Cumingii, 650
Cissus discolor, 108
 Citrus fruits, 170
 Clematis George Elliott, 727
Clerodendron cephalanthum, 652
Clematis montana, 727
Clianthus Dampieri, 397
Clintonia Andrewsiana, 805
Clivea miniata vars., 372
 Cliveas and Amaryllis, 522
 Clover and grass crops, 171
 Coal-tar in forestry, 238
 Cockroaches, to kill, 270
 Cocoa-nuts, 599
 Cocoa-nut shells as shades, 728
Cologlyne asperata, 172; *C. cristata* at Downside, 488; *C. c.* mountain form, 462; *C. c.* with semi-double flowers, 298; *C. elata*, 716; *C. lentiginosa*, 172; *C. Massangeana*, 242; Coffee at home, 76
 Coniferae, fruiting, 728, 807
 Conifers, flowers and buds of, 625, 754; for chalk, 231, 306, 307; on the Mediterranean coast, 306
 Conservatories, Indian, 424
 Cole, Mr. J., presentation to, 466
 Colens, the, 22
 Cologne Exhibition, 530
 Colonial notes, 14, 269, 599, 632, 775
 Colza culture in Normandy, 562
 Cornflowers, yellow, 807
 Corn, smut on, 396; see Smut
Coronilla glauca, 622
Corydalis tuberosa var. *alba*, 556
 County Government Bill, 660
 Covent Garden and the Duke of Bedford, 52; auctioneers and Salesmen's Association, 656; Club, 371; Life-Boat Fund, 466; market, 49
Cyperus alternifolius, 107
Crassula lactea, 296
 Crocuses, early, 234; vernal, 457
 Croton, the, 44, 174
 Cucurbit flowers, malformed, 597
 Cultural memoranda, 22, 50, 83, 107, 174, 235, 269, 302, 339, 366, 397, 493, 558, 622, 799
Cupressus Lawsoniana lutea, 724
 Curves of Inquiry on Walks, 779
Cyclamen Conm, 151, 180, 564; growing, 182
 Cyclamens in summer and autumn, 799
Cychnoches chlorochilum, 144
Cymbidium eburneum, 298; *C. elegans*, 331, 372, 403
 Cymbidiums, 303
Cyrtopodium Arthurianum var. *pallidum*, 268; *C. bellatulum*, 746; *C. caudatum*, 428; *C. Harrisonianum* × var. *superbum*, 235; *C. insigne* at Mr. Kimball's, N.Y., 369; *C. Io* ×, 12; *C. Meirax* ×, 172; *C. Morganæ* ×, 364; *C. oenanthem superbum* ×, 203; *C. Saundersianum* for £300, 113; *C. Spicerianum magnificum*, 106
Cyrtopodiums, seedlings of, 106; slipper of, 692
Cyrtanthus lutescens, 172; *C. obliquus*, 728
Cytisus filipes, 433; *C. racemosus*, and its vars., 523
- D.
- Daffodil names, too many, 469; natural hybrid, 658; nobilis and *D. variiformis*, 628
 Daffodils, 81, 488; and the frost, 524; double, 498; doubling, 561, 596, 659; natural hybrid, 658; time of lifting, 524
 Dahlia, the, 747
 Dahlias, new vars. of, 148
Daphne eueorum, 724
 Darwin's garden, 339
 Day's, the late J., Orchids, 594
 Dehérain, Mr., 82
 Dell, the, Egham, 714
Dendrobium capillipes, 746; *D. crassinode*, 364; *D. crepidatum*, 298; *D. endocharis*, scent of, 172; *D. hircoglossum*, 746; *D. Kingianum alba*, 800; *D. Quelchii*, 597; *D. rotiferum*, 235; *D. streblouae* var. *Rossianum*, 298; *D. superbiens*, 172, 203; *D. tetragonum*, 44; *D. Wardianum Lowii*, 268
Dendrobiums, 774; *D.*, seedling of, 428
Dentzia Wellsii, 562
Diapensia Lapponica, 308
Dichorisandra pubescens var. *tanienensis*, 557
 Dicksons, Chester, amalgamation, 623
 Dimorphism in *Tillandsia*, 717, 755
 Dinner-table decorations, 76
Diospyros Wieseneri, 363
Dipladenia boliviensis, 597
Disa racemosa, 592, 653
Discaria Toumatu, 801
 Disease by moulds, 334; finger-and-toe, 713; of Carnations, 151; of Chestnuts, 805; of Corn (see Smut); of Grapes, 137; of Impatiens, 267; of Onions, 755; of Oranges, 267
 Diseases of plants, 137, 267, 334, 396, 555
Disperis Fanninia, 557
 Douglasia, 524, 564
 Douglas Fir as a timber tree, 142
 Droppers, 276, 342
 Drying flowers in their natural colours, 82; of Orchids, 82
 Duke of Bedford and Covent Garden, 52
 Duke of Northumberland's new cottages, 339
 Dunes, planting the, 779
 Dunham Massey, plan of a garden at, 108
Duranta Plumieri, 44
Duranta, 149
 Durban Botanic Gardens, 299
 Dutch flower trade, 433
- E.
- Echinum callithyrum*, 653
 Economic Botany, 797
 Edinburgh Chair of Botany, 177, 275
Eichornia azurea, 22
Eichornias at home, 391
 Emigrants information, 433
 Emigration, 775
 Engleman's Botanical Works, 804
 English gardening, early, 741
Epidendrum bicornutum, 746; *E. ionosmum*, 716
Eranthemum pulchellum, 83
Eremurus bimaculatus, 596
Eriostemon obovallis, fl.-pl., 84
Erythronium albitorum, 556; *E. grandiflorum*, 597; *E. Hendersoni*, 652
Escallonia macrantha, 743
Eucharis amazonica, 50, 309, 403, 498, 566
Eucharis, diseased, 243
Eucalyptus at Whittinghame, 628
Eucalyptus unigera, 460, 595, 798; *E. coceifera*, hardiness of, 433, 798; *E. cordata*, 798
Eucalypti, hardy, 798
Eupatorium riparium, 493
Euphorbia Jacquiniflora, 107
 Evergreens, origin of, 373
 Export of plants to France, 369
- F.
- Fagraea zeylanica*, 728
Fagus purpurea roseo-marginata, 779
 Fergusia, 524
 Fern, Rat's-tail, 310
 Ferns, 270; Cooper-Foster collection of filmy, 177; crested, 179; the crossing of, 426, 457, 585; hardy, in pots, 265; tints in, 73
 Fertilisation of Beans, 694, 755, 781; of *Cattleya*, 208; of *Ilippeastrum* and *Tigrida*, 598
 Fertilising Moss, 23, 106, 140, 245
Ficus elastica, 108
 Field mice, 243; in gardens, 212
 Field of flowers, 659
 Fig trees, 277
 Finger-and-toe, 137
 Fir, Algerian, 140
 Fir, branches and squirrels, 597; destruction of the shoots of, 527, 564, 566, 596, 657
 Fish, Mr. D. T., 592
 Floral devices, 275; tea kettles, 338
 Florence and the Queen, 433; natural products of, 726
 Florida, gardening in, 679; market gardening in, 21
 Florists' flowers, 83, 110, 148, 207, 308, 430, 490, 620, 684, 747
 Flower garden, the, 22, 47, 79, 111, 150, 179, 211, 239, 271, 303, 335, 367, 399, 431, 463, 495, 527, 559, 591, 626, 655, 687, 719, 749, 777, 803
 Flower-holders, tubular, 780
 Flowers and light, 82; comparative anatomy of, 338; in season, 50, 176, 690; in South Ireland, 275
 Flowers of Conifers, 754
 Foliage-plants, a bed of, at Wilhelmshöhe, 83
 Foliation of trees, 427, 531
 Food and railway rates, 304
 Food for the people, available, 234, 336
 Food reform, 210
 Foreign correspondence, 116, 311, 626, 648, 715, 772
 Forest fire at Cape Town, 370
 Forest trees, effects of sea-water on, 366; ordered for Isle of Man, 242
 Forestry, 84, 142, 238, 366, 398, 435, 526, 654, 748; coal-tar in, 238; National School of, 147; school at Cooper's Hill, 455
 France, vegetation in the east of, 626
 François Lacharme memorial, 114
Fraxinus Ornus, 724
 Freesia culture, 83, 107, 152
Freesia refracta alba, 649
Freesias, 52, 119, 182, 235; at the Cape, 492; synopsis of, 588
Fritillaria, the, 776; *F. imperialis*, 596; *F. Mogridgei*, 652
 Frost, the, 339
 Fruit blossoms, hardihood of, 530; exhibition in Vienna, 521; for England, Victorian, 689; from Baltimore, 716; growers, conference of,
- G.
- 807; growers and salesmen, 530; growers of Hants, 626; packing, 751; prospects, 436, 660, 692, 693, 727, 751, 807; rates of transit, 499, 565, 531
 Fruit Register, 24, 363, 491, 748, 808
 Fruit season, the past, 182
 Fruit trees, 341; early mulching of, 724; hardy, 615; late flowering, 689, 565
 Fruits, copyright in seedling, 339; 372, 469; too many varieties of, 750; utilising waste, 730; under glass, 15, 50, 79, 111, 143, 175, 210, 239, 271, 335, 367, 399, 463, 495, 559, 591, 623, 655, 687, 719, 749, 777, 803
 Fuchsia, the, 50; *F. glabe*, 808
 Fuchsias, exhibition, 183
 Fungi and insects in crops, 306; parasitic, 354
- H.
- GALANTHUS* Sharlocki, 243
 Gardener emigrants, 243, 276
 Gardeners, emigration of, 775; education of, 659; Orphan-Fund, 85, 113, 152, 180, 211, 274, 369, 401, 432, 561, 592, 624, 656, 688, 785; fête, 720, 751, 804
 Gardeners' Royal Benevolent Institution, 49, 56, 80, 689, 778, 804
 Gardenias, 269
 Gardening, Early English, 741; future of, 295; in Addison's time, 583; periodicals, 11; ruder difficulties, 13
Gentiana acaulis, 598; varieties in, colour of, 554
Genista racemosa, 622
Gerbera Jamesoni, 775

MESSRS. PROTHEROE AND MORRIS will include the above by AUCTION, at their Central Sale Rooms, 67 and 68, Cheapside, London, E.C., on WEDNESDAY and SATURDAY NEXT, at half-past 12 o'clock each day.

On view morning of Sale, and Catalogues had.

Friday Next.

ESTABLISHED ORCHIDS.

MESSRS. PROTHEROE AND MORRIS will include the above by AUCTION, at their Central Sale Rooms, 67 and 68, Cheapside, London, E.C., on FRIDAY NEXT, January 13, at half-past 12 o'clock precisely, a very fine assortment of well-grown ESTABLISHED ORCHIDS, chiefly in Flower and Bud. Also 2200 established plants of ODONTOGLOSSUM ALEXANDRE, imported from the best district about four years ago. The plants are healthy, such of them as have flowered have been the finest varieties. Fine established plants of LÆLIA ANCEPS ALBA, in spike, ORCHID BASKETS, &c.

On view morning of Sale, and Catalogues had.

Friday Next.

ODONTOGLOSSUM ALEXANDRE of the best type, from Messrs. Shuttleworth, Carder & Co. MESSRS. PROTHEROE AND MORRIS will include in their SALE by AUCTION on FRIDAY NEXT, January 13, a very fine importation of ODONTOGLOSSUM ALEXANDRE, in splendid condition, and including numerous large masses; also ODONTOGLOSSUM VEXILLARIUM, &c.

On view morning of Sale, and Catalogues had.

Flowering Orchids.—Special Sale, January 31.

MESSRS. PROTHEROE AND MORRIS desire to announce that their next SPECIAL SALE of ORCHIDS in FLOWER and BUD will take place as above, for which they will be glad to receive notice of Entries as early as possible.

Eltham.—Expiration of Lease.

Important CLEARANCE SALE of General NURSERY STOCK, extending over upwards of 30 Acres of Ground. MESSRS. PROTHEROE AND MORRIS are instructed to SELL by AUCTION, on the Premises, Todman's Nursery, Eltham, Kent, about the middle of FEBRUARY NEXT, the First Portion of the extensive stock of EVERGREENS, CONIFERS and DECIDUOUS SHRUBS, FRUIT, ORNAMENTAL, and FOREST TREES, particulars of which will shortly appear.

Monday Next.—(Sale No. 7592.)

IMMENSE IMPORTATIONS from JAPAN. 20,000 Grand Bulbs of LILIU AURATUM, lotted to suit large and small buyers (some in cases as received); 60 cases of LILIU SPECIOSUM ROSEUM as imported, 1000 L. SPECIOSUM ALBUM, 2000 L. LONGIFLORUM, 150 CYCAD trunks, 7000 NARCISSUS, DRIED GRASS, &c., from Japan; also a fine lot of LILIU GIGANTEUM, and many other Home-grown LILIES, South African TUBEROSES, LILY of the VALLEY in Clumps and Crowns, DUTCH BULBS, &c.

MR. J. C. STEVENS will SELL the above by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on MONDAY NEXT, January 9, at half-past 12 o'clock precisely.

On view morning of Sale, and Catalogues had.

Wednesday and Saturday Next.

First-class Pyramid and Dwarf-trained FRUIT TREES of sorts, Ornamental SHRUBS and CONIFERS, Standard and Dwarf ROSES to name, including many of the leading varieties; CARNATIONS, PICOTEES, PINKS, and other BORDER PLANTS, LILY of the VALLEY in Clumps and Crowns; SIKKENS, Home-grown LILIES, GLADIOLI, and many other BULBS and ROOTS.

MR. J. C. STEVENS will SELL the above by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on WEDNESDAY and SATURDAY NEXT, January 11 and 14, at half-past 12 o'clock precisely each day.

On view mornings of Sale, and Catalogues had.

Thursday Next.—(Sale No. 7593.)

CATTLEYA CRISPA.

LAWRENCEANA.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY NEXT, January 12, at half-past 12 o'clock precisely, by order of Mr. F. Sander, a fine importation, just arrived, of the grand and showy CATTLEYA CRISPA, with large bulbs and broad, distinct-looking leaves; also a very fine lot of C. LAWRENCEANA: this beautiful Cattleya is extremely rare in its native country, and one of the finest of the genus; it has received the award of the Certificate, and has been the admiration of all beholders, being the most lovely formed and glowing of all Cattleyas.

A quantity of ORCHIDS also will be offered from the Roraima Mountain, the whole in extra condition, including a splendid lot of Zygopetalum rotundatum, Honletia species, Scutellaria, probably new; Oncidium fonsianum, Maxillaria species, Brassia species, Bifrenaria species, Oncidium Marshallianum, and many other fine ORCHIDS.

On view morning of Sale, and Catalogues had.

Orchids in Flower and Bud.

MR. J. C. STEVENS begs to announce that his next SALE of ORCHIDS in Flower and Bud will take place at his Great Rooms, 38, King Street, Covent Garden, W.C., on WEDNESDAY, January 18, at half-past 12 o'clock precisely, and he will be glad if gentlemen desirous of entering plants for this sale will send list not later than Thursday next.

Wednesday, January 18.

CATTLEYA EXONIENSIS, splendid plant of the fine long-leaved variety, in 15-inch pan, in flower.

MR. J. C. STEVENS will include the above in his SALE by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on WEDNESDAY, January 18, at half-past 12 o'clock precisely.

On view morning of Sale, and Catalogues had.

Home Counties.

FLOWER AND VEGETABLE SEEDS

DIRECT FROM THE FIELDS!

CANNELL'S
NATURAL

NATURE makes it an IMPERATIVE FACT that KENT possesses a more favourable CLIMATE and SOIL than any other county in England (perhaps even in Europe) for the production and RIPENING of Seeds, also in COLOURING, BRIGHTNESS, PLUMPNESS—the Force of Life or Germinating Power stronger to withstand unfavourable weather, and far MORE PROLIFIC. Coming from a calcareous subsoil, the thorough change (SO ESSENTIAL) makes the yield of our seeds marvellously rich and productive. Further, we are determined that the purchaser shall have the CHOICE and ADVANTAGE of Seeds DIRECT from the ACTUAL GROWERS, and thus avoid the risk and deterioration where seeds are bought

CANNELL'S
ADVANTAGES.

and sold half-a-dozen times between the SAVERS to the SOWERS. Our Illustrated Catalogue for the Garden contains a vast amount of invaluable information on high-class culture and gardening, and enables amateurs to be supplied with the BEST of all WANTS FROM THE GROWERS. Replete with 550 Engravings, Two large Views of our SEED FARM, THE TWO HARD WORKERS, and Three magnificent COLOURED PLATES of New and Improved Plants and New Invaluable Vegetables—so important to successful prizetakers. The whole are really a gift to the nation.

Post-free to Provisions, Present, and Coming Customers.

CATALOGUE,

embellished with

109 ENGRAVINGS,

(many of which, like the flowers they illustrate, are original),
consisting exclusively of**FLOWER SEEDS.**

I have much pleasure in announcing that my New CATALOGUE of Flower Seeds is just finishing, and will, as received from the printers, be Posted to my Customers, who will doubtless welcome it as a valuable Catalogue for reference, and to whom I am sure, it will prove especially instructive and attractive. Considering that its pages are devoted to Flower Seeds only, it is perhaps not too much to claim, that it is the LARGEST CATALOGUE of these ever published, and includes in its varied columns very many species and varieties, which can be procured from Tottenham only; and while desirous to introduce a large amount of stuff not generally known, I have—as is my wont—had due and proper regard to the fact, that as a rule buyers do not care for specialties unless they are distinct and effective. All the novelties and varieties appearing in this Catalogue claim such a distinction.

Copies may be had Gratis and Post-free
upon application.

**USEFUL NOVELTIES
OF THE SEASON.**

LAXTON'S "EARLY WILLIAM" PEA.—
An early dwarf William 1st. Ten days before the
ordinary trade stock, and as tried at Chiswick, only
2 feet 6 inches high, 2s. 6d. per Pint.

LAXTON'S "HOWARD" PEA.—Between
Supreme and Ne Plus Ultra. A large and splendid Show
and Quality Pea, and the hardest and best of all for
market. 4 feet. 2s. 6d. per pint.

LAXTON'S "OPEN-AIR" TOMATO.—
The earliest to ripen outdoors. Awarded x x x for First-
class Certificate, after trial at Chiswick, against eighty
varieties; fruit handsome and good, does not crack; plant
sturdy, a very free producer, and the best disease resister.
1s. 6d. per packet.

LAXTON'S "SANDY PRIZE" ONION.
The finest and truest of the White Spanish type. Re-
commended after trial at Chiswick of upwards of sixty
varieties. Half-ounce packet, 1s.

**LAXTON'S "CZAR" GIANT RUNNER
BEAN.**—By far the largest, broadest, and best of all the
Runner Beans. F.C.C. at Shrewsbury. 2s. per packet.

LAXTON'S "BEDS HERO" POTATO.—
Between White Hebron and Myatt's—the best main-crop
Kidney. 2 lb. 2s.

LAXTON'S "BOUNCER" POTATO.—
F.C.C. after trial at Chiswick. A large, handsome, and
most productive white round winter Potato, to supply
the place of the Regent. 2 lb., 2s.

LAXTON'S "REWARD" POTATO.—
Between Champion and Magoum Roum. A splendid
quality late round, good till June, shallow-eyed, robust,
and most productive. I look upon this as one of the very
best out of 1000 Seedlings, and have named it accordingly.
2 lb., 2s. 4 lb. of each of the above Potatoes, free on rail,
for 10s. 6d. post order.

**LAXTON'S "INVINCIBLE BLUE"
SWEET PEA.**—The best blue, and the most distinct
colour in Sweet Peas yet issued. 1s. 6d. per packet.

LAXTON'S CARMINE ASTER.—The most
brilliant-coloured of all Asters; habit half dwarf. 1s.
per packet. Both gems for the florist.

The Seeds in Packets only, sealed with my name
and address.

LIST, with full particulars of the above, and
upwards of 100 of the best Novelties and Speci-
alties in Vegetable and Flower Seeds, sent free on
application to

B.S. WILLIAMS

NOVELTIES FOR 1888.

THE FOLLOWING SPLENDID NOVELTIES are my own introductions for 1888, and are now offered for the first time. Sold only in Sealed Packets bearing my Trade Mark:—

AGERATUM, "ADA BOWMAN" (new).

This new variety was raised at Hylands Park three years ago. It is without doubt the finest Ageratum grown for bedding purposes. It blooms in masses from the time of planting out until it is cut down by the frost, and requires no pegging down, as it is only 9½ inches high; the trusses measure from 6 to 7 inches across. It is of a very effective and telling delicate blue colour.

It is a most valuable acquisition when propagated in pots in the autumn for early winter flowering. Its freedom in blooming is so pronounced that each pot is quite a ball of flower, and continues so to the middle of January.

Per Packet, 1s. 6d.

PRIMULA SINENSIS FIMBRIATA, "MAGENTA QUEEN" (new).

This new variety is of very compact habit of growth, very vigorous and robust; the leaves are of a dark green colour. The blooms are very large, measuring upwards of 2½ inches in diameter; they are of very good substance and a bright magenta, with a small bright lemon eye. It is quite a new colour in Primulas, and its distinctness is very pronounced when associated with other kinds.

Per Packet, 5s.

STOCK, INTERMEDIATE, WILLIAMS' "CRIMSON GEM" (new).

This variety, on account of its charming and decided colour, is an acquisition of considerable merit, as it is a great advance in richness and brilliancy of colour upon any known kind of Stock. It will be found very serviceable for spring bedding, window boxes or pots, where it will produce a wonderfully fine and pleasing effect. It is of a dwarf compact habit; the central spike and lateral branches produce a great profusion of very rich crimson blooms of very large size.

Per Packet, 2s. 6d.

MELON, HAMSTEAD PARK SEEDLING (new).

This fine new variety is a cross between *Golden Perfection* and *Victory of Bristol*. The raiser speaks very highly of it, and says that it does as well in a pit as in the Melon-house. It is a first-rate setter and a very strong grower, and never shows any sign of canker at the collar. It is round in shape, very hand-some, and beautifully netted. The flesh is of a very pale scarlet colour, about 3 inches in depth, with very delicious flavour. The fruit weighs from 4 to 6 lb. each.

Per Packet, 2s. 6d.

ILLUSTRATED

SEED CATALOGUE FOR 1888

Is now ready, and will be forwarded Gratis and Post-free to all applicants.

As a Supplement TO THE GARDENERS' CHRONICLE FOR Next Week, Jan. 14, WILL BE Published an Ink-Photograph, REPRESENTING "THE FERNERY" at Nash Court, Faversham.

In the same Number will be published a LIST of the PRINCIPAL HORTICULTURAL SOCIETIES of the KINGDOM, with names of their Secretaries, &c.

THE Gardeners' Chronicle.

SATURDAY, JANUARY 7, 1888.

THE ROYAL HORTICULTURAL SOCIETY.

AS one who took a great interest in the Royal Horticultural Society in the palmy days, when its meetings were held in Regent Street, and who well remembers the dismay and forebodings with which its migrations to South Kensington were regarded by some of its enlightened Fellows, I may be allowed to express the satisfaction with which I view the prospect of its return to its old ways, and my confidence in its future justifying the anticipation of those who urge such means for its restoration to prosperity.

My position as an Honorary Fellow of the Society (a distinction of which I am very proud), whilst, on the one hand, it debars me from taking a part in its business affairs, on the other it encourages me to look with keen interest on all projects for its welfare, and to endeavour to make others do so too. And to this end I have for a good many years past ventured to urge upon some of its officers and most influential Fellows the necessity of reverting to the practices of old, if they would see the Society replaced in a position of independence, and resume its legitimate functions.

It is not horticulturists only whose sympathies are enlisted in the present movement, but botanists and agriculturists; and these are all, in so far as my inquiries enable me to judge, agreed as to the chief desiderata for the reconstruction of the Society on a satisfactory basis. They are—meeting rooms in a position as accessible to Fellows as those in Regent Street were, and the obtaining the whole time and energies of an efficient permanent Under-Secretary.

The meeting room (which should be in connection with the Library and Council and officers' rooms) should be, not only a convenient, but an attractive place of resort for the Fellows, where something of interest might always be seen

on ordinary as well as on show days. To this end Fellows should be encouraged to send rare, curious, and ornamental plants for exhibition (not necessarily for competition) on any day of the week, though naturally preferring a show day if that were convenient, which it often is not. And the room should be provided with some glazed cases, in which the plants could be put when the rooms are cleaned, so that they should suffer as little as possible from the dust and drought of the metropolitan climate. If there were always something to see in the rooms, not only would the Fellows frequent them, but by bringing their friends they would tend to swell the ranks of Fellows. The gardens at Chiswick might be largely utilised towards this object.

The permanent Assistant-Secretary should be an officer with a fair amount of botanical knowledge, especially of cultivated plants, and who could thereby aid visitors in naming specimens brought for this purpose, and be some check upon the appalling grievance of nomenclature that too often disgraces the exhibitions, and excites the wonder of foreigners. The editing of the Journal should be under the Assistant-Secretary's control, and be one of his chief duties.

I am constantly told, when urging the necessity of such an Assistant-Secretary as I have here indicated, that there is no such phoenix to be found. This is perhaps true in so far as a ready-made one is concerned, but I am confident that there would be no difficulty whatever in creating one, even *pro re nata*. Kew has had no difficulty in finding for foreign, Indian, and colonial botanical gardens, gentlemen who would have distinguished themselves as efficiently and highly as an Assistant-Secretary of the Royal Horticultural Society as they have done in their present offices, and for the duties of which offices none of them was altogether prepared when they were first undertaken. There is no lack of gentlemen with the necessary botanical training who, by the aid of the Lindley Library, visits to Kew and the principal horticultural establishments in the vicinity of the metropolis, might be expected rapidly to acquire the requisite technical knowledge of plants. Lindley did not culminate in a day; he grew in knowledge with the growing needs of the Society; and though we may not look for an Assistant-Secretary who would combine, as he did, with the duties of that office a Professorship of Botany, a first-rate position as a scientific botanist, and a voluminous author, we may reasonably expect to obtain, for a fair salary, an efficient and in every way satisfactory official. *J. D. Hooker.*

HALF-HOLIDAY IN GRENADA.

LAND travelling in this island, where there are no roads to speak of, is done on horseback by all white people, and such coloured inhabitants as can afford it. Luggage is carried on the heads of negroes, who can go long distances with heavy burdens. The horses are a very mixed race, but though not much to look at, as a rule, they are very sure-footed. A West Indian horseman, as a matter of course, traverses places where no one else would ever dream of going. Ordinarily on inland journeys I have been mounted on a quiet mare called the Lady Rowena, but better nicknamed "the Camel," and have had an additional assurance of safety in the instructive and pleasant companionship of the Government botanist, who is founding a garden and exploring the flora of the island. He has gone, however, to the north of the island for a

week or more, and my sheet-anchor, the popular Camel, has been hired by a fortunate resident. There are not many other horses to choose from, and ultimately I select an animal which I have hitherto known only as "the cat's-meat horse." This was not done without deliberation. It has the recommendation of having been habitually ridden for some time by a naval officer on shore. Trusting, therefore, that it has thus become accustomed to a free-and-easy kind of equitation, and knowing that it has carried a seafaring man without mishap, I feel a certain confidence in this companion of my lonely ride into the interior.

I go without guide, porters, or collecting equipment of any kind, since the trip is intended merely as a forenoon's relaxation from more serious business in the shallow seas. In the early morning my men come to me and I appoint a bay in the south-west of the island where they are to meet me in the late afternoon with the boat, carrying with them a boy to bring the horse back. Skirting the lagoon and passing negro gardens, or provision grounds, as they are called, I note *Carica papaya* (the Papaw tree), the juice of which has the property of rapidly rendering tough meat tender. In tropical countries, where no great time elapses between the killing and the cooking of an animal, this tree has a great culinary value. A preparation of the juice has recently been found to yield valuable results as a drug. Among the other plants to be found here is *Sterculia acuminata* (the Kola-nut), brought doubtless by the negroes from Africa, which has also valuable medicinal properties. The one, perhaps, that has made it most famous is the power this nut possesses of quickly sobering drunken people.

This lagoon, which is separated from the carenage of St. George by a coral reef, a few feet beneath the surface, is the crater of an old volcano, which is said to have swallowed at least part of the original French settlement. After sharper shocks of earthquake than usual the inhabitants are wont to regard it anxiously, and having explored its depths with a dredge, I can sympathise with their anxiety in one respect. If one is to be bombarded by a volcano, one would prefer not to have insult in the shape of foul water, barbaoutas, and fathoms of liquid mud added to the injury. My horse here has the misfortune to step on and maim a young chicken, and immediately the owner and several sympathising female friends are upon me. I give her compensation, with which she is so much pleased that I am at once offered the chicken's "mother" a "fair bargain." Considering the value of this fowl I reluctantly decline. There is hardly a chicken, I am assured, anywhere about but owns this one as its parent; the eggs it has laid are beyond number, and, not only the owner, but the neighbours have had this notable fowl under observation for years. Neglecting this excellent opportunity of testing the value of the juices of the Papaw tree, I urge on my way, which soon brings me to the path that leads inland.

Following the path, which is deep in mud owing to heavy rains last night, I come out on an open grassy space, more like an English park than any other tropical scene I have met with. Over the damp grass a few large crabs are crawling—a sight that is hardly in keeping with the thoughts conjured up by the appearance of the place. Here, however, crabs migrate, as is well known, in large numbers to a great elevation in the mountains. Passing a thick cove, in which there are growing a few trees of the sort that furnishes the "swizzle stick" used in churning the pernicious but excellent "cocktail," I

go off my route a little way to the right, to get a view of country new to me. This leads me—of all places in the island—to the colonial racecourse. Looking at the "cat's-meat horse" I think of my own accomplishments, which are confined to the useful faculty of sticking on. It has apparently some sense of shame left, too, for with one accord we hasten from the spot.

The next part of my way leads through dense bush, which I had been told was cleared. Evidently there had been at no distant date a good road, for these parts, underneath; but the bush, which springs up here with extraordinary rapidity, has obliterated all apparent trace of it beyond the not very noticeable fact that the vegetation along this track is not so high as the surrounding bush. Pushing through it with much scratching and tearing, in spite of careful selection of the way, I come at last to the place where the work of clearing is going on. A band of negroes armed with big curved cutlasses are resting from their labours in groups among the fallen branches, which for the present more effectually block the way than they did before being cut down. While a passage is being cleared for me I have a chat with the foreman of the gang, who contrasts very graphically the rapidity of the growth of the vegetation with the dilatoriness of the negro who cuts it down. He is himself very nearly as black as his men, but on the strength of a dilution of his blood by some remote white ancestor, which the "swamping effect" of intervening close breeding with the primitive stock of Ham has well nigh effaced, he ranks himself as a white man, and has more than the ordinary white man's contempt for his coloured friends.

Our talk is interrupted by an agonising scream from a negro, who makes towards us, the picture of abject terror. Nothing but a jumbie (ghost) or a serpent could produce such an effect, and I accordingly seek the spot on foot, armed with the foreman's stick. The negroes have one and all cleared out of the fallen bush, and the foreman's ancestor evidently was no naturalist, for he shows the common repugnance to reptiles. I am just in time to witness the retreat of a great red snake with slate-coloured spots among the branches. However, I soon come up with him, and one good blow breaks his back. His head and teeth proclaim him a constrictor, and an animal more likely to do damage to the negroes' live stock of the smaller sort than to his person. He now reposes with others of his kind in the Natural History Museum. After this my difficulties with this sorry horse increase. It is plainly aware of the fact that I am carrying the snake tied up with a string, and it strongly objects to this addition to the party. I conclude that, like Heine's donkey in the *Harzreise*, its ancestors must have eaten forbidden oats in Paradise, and that the snake is too suggestive a reminder of the fact. I accordingly take the first occasion of meeting a negro's cabin to dismount, and, seated outside, eat my breakfast. The owner furnishes me with a Cocoa-nut, the clear fluid of which mixed with a little whiskey is very refreshing. The snake is then coiled up in the bag, in the bottom of which my breakfast had been carried. This arrangement satisfies my travelling companion, and crossing a swamp by a good firm track with only one ford to pass, I gain the region I have come particularly to visit.

The land vegetation of this island is distributed in two great zones—one occupying the central mountain mass of extinct volcanos, and the other the lower grounds and maritime region. The "high woods" of the mountains form that part which we have more especially in the mind when we speak of a tropical forest (see *Gardeners' Chronicle*, June 25, July 2 and 9, 1887). Mountain Palms, graceful Tree Ferns, giant Silk-cotton trees, and numberless others here raise domes of foliage far aloft, while from their branches hang down masses of lianes and lialines, and the whole is abundantly festooned with a wealth of creepers and epiphytic plants such as Orchids, Balisiers (*Heliconia*), Ferns, Fern-allies, mosses and lichens are scattered everywhere, and the whole forms so dense an entanglement that the traveller has ordinarily to cut his way through it step by step.

To reduce degrees C. above zero to degrees F., double the number, deduct one-tenth and add thirty-two.

To reduce degrees C. below zero to degrees F., multiply by two and a quarter and add thirty-two.

To reduce degrees K. below zero to degrees F., multiply by two and a quarter and deduct thirty-two.

To reduce degrees F. to degrees C., halve the number of degrees above, or below thirty-two and to that add one-ninth of the same.

To reduce degrees F. to degrees K., proceed as above, but deduct one-ninth instead of adding.

TIMBER MEASURE.

To FIND THE AREA OF A BOARD OR PLANK.—*Rule*.—Multiply the length by the mean breadth of the area. *Note*.—When the board tapers add the breadth at the two ends together, and take half the sum for the mean breadth.

To FIND THE SOLID CONTENTS OF SQUARED TIMBER.—*Rule*.—Multiply the mean breadth by the mean thickness, and the product by the length, for the contents.

To FIND THE SOLIDITY OF ROUND OR UNSQUARED TIMBER.—*Rule I*.—Multiply the square of one-fourth of the mean circumference, or of the mean quarter girth, by the length, for the contents. *Rule II*.—Find the area corresponding to the quarter girth in inches, and multiply it by the length of the tree or piece of timber in feet, then will the product be the solidity in feet, and decimal parts of a foot, according to Rule I.

Note.—When a tree tapers regularly the girth may be taken at the middle for the mean girth, or it may be taken at both ends, when half the sum will be the mean girth. When a tree tapers irregularly, being thick in some places and small in others, the girth may be taken at the ends, and at equal intervals, then the sum of the girths, divided by their number, will be the mean girth; or the tree may be divided into several lengths, and the contents of each part computed separately, then their sum will be the contents of the whole tree.—*Pardon's Almanack.*

COVENT GARDEN MARKET. They vary also in size, some according to the kind of fruit or vegetable they contain, and some according to the time of year and size of the articles they contain. It is, therefore, almost impossible to convey an accurate impression of these measures; but the following will be useful to those who are interested in Covent Garden quotations.—

A sieve is understood to be about 15 inches in diameter and 8 inches deep, and to contain 7 imperial gallons; half-sieve, 3 1/2 gallons; quarter-sieve, 1 1/2 gallon. A bushel basket is 17 1/2 inches in diameter at top, 10 inches deep, and 10 inches in diameter at bottom. When heaped, it is supposed to contain an imperial bushel. Punnet; for Seakale, 8 inches in diameter at top, 7 1/2 at bottom, and 2 inches deep; for Mushrooms, 7 inches in diameter and 1 inch deep; for salads, 5 inches in diameter and 1 inch deep.

A bunch of Radishes varies from one dozen to two dozen roots, according to the season.

A bundle of Asparagus contains from 100 to 150 heads.

A bundle of Rhubarb from 20 to 30 stems.

A bunch of Carrots, 12 and upwards.

A bunch of Turnips, 12 and upwards.

A bunch of Leeks, 6 and upwards.

Bunches of Greens and of herbs vary much, according to kind, size, and season.

Roll of Celery = 6, 8, to 12 heads.

A tally = five dozen.

A score of Lettuce or Endive = 22.

LINDLEY LIBRARY.

This Library is held in trust for the Royal Horticultural Society, in whose rooms it is deposited. Under certain conditions, it is open not only to the Fellows of the Society, but also to the general public. The Trustees are the Secretary and Treasurer of the Royal Horticultural Society *ex officio*, and the following gentlemen:—Dr. Robert Hoag, Dr. Maxwell Masters, F.R.S.; G. Maw, Esq., F.R.S.; and H. J. Veitch, Esq.

ARTIFICIAL MANURES AND THEIR APPLICATION.

[P.T.O.]

This is the haunt of the monkey, the seven-banded armadillo, more especially of the humming-birds, and such other forms as one associates with the tropical forest.

My expeditions into the interior have naturally led me for the most part to this happy hunting-ground, and such expeditions cannot be reasonably done under two days. But the vegetation of the lower ground, unimpressive as it looks beside the high woods, has its beauties and its interests. The Cocoa-nut and other Palms, the Flamboyant tree (Poinciana), the Bread-fruit, the Mango, the Cacao, and many other forms, for the most part cultivated or escaped from cultivation, and largely introduced from other lands, mix with an indigenous flora, which certainly is not particularly taking to the eye. Whether from contrast with the stately trees of the "high woods" or not, this flora of the lower ground gave me the impression of a general scrubby look, relieved here and there by towering Palms. The traveller appreciates the beauty of our northern Pine trees never so fully as when fresh from tropical scenes.

It is as little my intention to attempt any detailed picturesque description of tropical vegetation as it is to give a scientific account of it. Kingsley in *At Last* tried to tell us of the beauties of the neighbouring island of Trinidad and the result, even in the case of that master, was a warning to those who feel tempted. To oscillate between a riotous excess of adjectives in all degrees, and a bare recounting of names which are Greek (and many of them bad Greek) to the ordinary reader is but poor entertainment. I shall therefore take my way with a lighter heart if with a lighter head as well.

The narrow track leads me upward, and the journey is interrupted now and then by dismounting to examine this or that. I come at last to a bare grassy ridge, from which a wide view is obtained of the lower ground, the bays and headlands and the shining sea beyond. Below the south-west horizon lies the island of Tobago—Cruise's island of fancy though as real a place in the minds of all of us as most we have set foot in. It was from these very bays on which I am now looking that the cannibal Caribs set out on those expeditions which culminated in banquets on his shore. On these very slopes are still picked up the arrow-heads and other stone weapons with which the victims were dispatched. From the brothers of these trees were hollowed out their war canoes, but the people themselves have gone, and in a fashion worthy of men with a true contempt for death. In the north of the island (as was noted in a previous article) there is a high rock (Morne des Sauteurs), from which well-nigh the last of the Grenada Caribs leapt into the sea when beaten by the French in an infamous war of extermination. A scattered remnant still survives in neighbouring lands. In Dominica, at least, a number of the Carib inhabitants lead a shy and remote life in the forests, rarely appearing to the faces of the white and black usurpers of their ancient possessions. There is said to be a mystery hanging over the relationships of this people, so strikingly unlike their original neighbours. Some have supposed, under the seductive influence of a hare-brained kind of comparative philology, that they are a stock akin to the Arabs, and that their ancestors were drifted across by the trade winds while on a voyage on the North-West African coast. There has been modern demonstration of the fact of such driftings of people in boats, and Martyr mentions that at a place called Quarequa, in the gulf of Darien, Vasco Nunez met with a colony of negroes. Besides, in all probability Columbus was not "the first to cross the main," since he is said to have discovered the stern-post of a vessel on the shore of Guadeloupe. I venture to think, however, that

"His stones and his bones and his bows"

are grave inconsistencies with this theory of Carib degeneration from an Arab people which built ships, or, at all events, such large boats as enabled them to cruise in the North Atlantic. The Caribbees (whence the names Galibis, Calibis, Caliban) were, it is stated, a powerful people on the mainland of South America, and we may rest content with that without seeking

their origin farther afield. At all events this is one of those cases in which prophecy is more certain than history. In a few generations this formerly strong and warlike race will be buried with whatever mystery surrounds its origin.

My route now lies downward to the coast, and on the way I pass a group of negroes' cabins. In the garden of one there is lying a child's coffin. It seems a strange custom to expose this sad object to the dangers of the wilderness. On a previous occasion I had wasted much sympathy on the sorrowing parents until I learnt from His Excellency's *aide-de-camp* that such coffins hold no corpse, but belong to the scarecrow family, and are designed to avert robbery!

Two boys, as black as they may be, without a scrap of clothing, dart off at my approach, and their playfellows, a couple of pigs, follow them under the paternal roof. Just before I reach the bay, while passing over an open grassy field, once a cane field, no doubt, in the days when sugar-planting was carried on in the island, I note a bird very like, if not, the cowbird (*Molothrus pecoris*), perching on an ox, and making short flights meanwhile about its head. It appears to be feeding on the insects disturbed by the animal as it moves among the grass, but it may well supplement its diet by relieving the beast of parasites.

There is no sign of the boat in the bay as yet, and my hopes of dredging wane with the afternoon. The steamy heat is nearly insupportable, and is alleviated only by the malignant attacks of a cloud of mosquitos. This is the only known use of mosquitos! They keep one from thinking exclusively of the heat. Since they are like this in the afternoon, I try to imagine what they must be at night should any poor wretch have to sleep here. There is a legend on this coast to the effect that three benighted travellers were bitten through an inverted sugar-boiler beneath which they had taken shelter. In despair I begin my journey, and when well round the bay come upon a vile smelling creek, where the boat is lying with its crew fast asleep, the whole carefully hid from view. I speak to them about this. The boy mounts the horse, and we are off. Once outside, we are soon in the current, and rapidly making for home. They had not been asleep all the afternoon, since my diver has a few jars full of specimens. He tells me of them—using mostly his own names for each—and the depths at which they were found, in which I have never found him mistaken. He is especially fascinated, however, with the scientific names of the plants and animals searched for by sea and land, and I verily believe if he ever beget a daughter she will be called—according to the negro taste for "fine names"—*Rhipilia Peripatus White*. *George Murray*.

NEW OR NOTEWORTHY PLANTS.

ÆRIDES DIFFORME, *Wall.*

I HAVE already spoken of this rare and exceedingly striking Orchid, with its sun-like anterior lip, as far back as 1865 (*Gardeners' Chronicle*, 1865, p. 698), when I had it from Messrs. Hugh Low & Co. It was received later in the Hamburg Botanic Garden, where it flowered in July, 1875. I am very sorry that I kept no records as to the colours of the flowers of those plants. Sir Trevor Lawrence, Bart., M.P., kindly favoured me with an inflorescence in July, 1878. The flowers were yellowish-green; the sepals and petals had some nearly parallel cinnamon stripes on the inferior halves internally. The side lacinia of the lip are cinnamon, with similar lines on the greenish-yellow spur. There are some cinnamon lines at the base of the column, which is yellowish, with a brown border to the androclinium, and a similar zone in the middle of the infrastigmatic part.

Finally, M. Regnier, 44, Avenue de Marigny, Fontenay-sous-bois, Seine, has kindly sent me a very fine inflorescence, a foot long, covered with very deeply

coloured flowers. Sepals and petals yellowish-ochre, coloured with long cinnamon nearly parallel stripes, reaching to the top. Side lacinia of the lip yellowish, with six to seven mauve-purple bars. Mid-lacinia reddish mauve-purple, ultimately darker reddish. Spur reddish, light. Column reddish-brown at the back, and with a similar zone transversely over the centre of the infrastigmatic area. It is very pretty, and was imported, as I learn from M. Regnier, from Siam. The area of the species is very wide. I have only to repeat that I cannot distinguish *Ærides hystrix* as a distinct species. Its colours, noted by Dr. (now Sir) J. D. Hooker in Sikkim, correspond very well with those of Mous. Regnier's plant. *H. G. Rehb. f.*

ERIA NICOLON, *Lindl.*

Mr. S. Courtauld, Bocking Place, Braintree, has been so kind as to send me a fine specimen of this lovely plant, which was described by Dr. Lindley in 1830 from materials given him by Macrae. I had never seen a living plant before, neither have I any note about it. I learn from Mr. S. Cortauld that this fine gem (for a gem it is, as we have to inform the lovers of *Cattleyas*, *Odontoglossums*, and *Cypripediums*) is called by the English the Cingalese Lily of the Valley. This name may be explained by the inflorescence of one-sided white flowers, though the contrast between these with the white bracts and the dark purple pedicelled ovaries and rachis is far more striking than anything in *Convallaria majalis*. At all events the comparison is not so good as that of the greenish *Polystachya* inflorescence with *Mignonette*.

The stem itself is rather strong, very tumid at its base, covered there with wide brown sheaths, generally half a span long. There are from five to seven narrow cuneate, lanceolate, acuminate, very stiff leaves of the stem's length, which stand nearly upright at the top. Under these stand the inflorescences, probably usually two. Their main rachis is of a fine dark purple colour and velvety. The triangular acuminate bracts are deflexed and snow-white. The stalked ovaries are in colour and pubescence like the main axis. The flowers themselves are of the purest white. I can only see some purple at the superior part of the column. The very base of the column, with the adnate base of the lip, is filled with honey. The chin is blunt. Sepals triangular acuminate. Petals narrower. Lip sigmoid, trifid, side lacinia blunt, mid lacinia acute. There is no trace of any keels or ridges, which appear only in dried specimens.

My wild specimens are from Gardner, 860! Thwaites, 2982! Dr. Wallace, of Colchester, sent me wild specimens, so he may have the plant, which was also collected by the late Wawra von Fernsee whom science lost so early last year.

What I see in Mr. S. Courtauld's fine specimen is not quite what Dr. Thwaites said, who stated (*Enum. Pl. Zeyl.*, 299), "columna labelloque ad basin plus minus rubro tinctis." There may be varieties. *H. G. Rehb. f.*

FIGUS CANONI, *N. E. Br., n. sp.*

This is the plant that was introduced in 1875 by Mr. W. Bull, and described and distributed by him under the name of *Artocarpus Canoni*. There is no doubt that during the twelve years it has been in cultivation it has flowered elsewhere than at Kew; but having recently flowered there, the Assistant-Director, Mr. Morris, at once perceived that it was not an *Artocarpus*, but a true Fig, and kindly placed it in my hands for identification, and having failed to recognise it as a described species, I name it as above; and I may say, that had the plant in the first instance been placed in the hands of a botanist it would not have been erroneously referred to the genus *Artocarpus*. The plant is too well known to need much description, but it may be noted that when in a young state the leaves are more or less lobed in a pinnatifid manner; when older the leaves are entire and ovate or ovate-oblong in outline; in both entire and lobed leaves the apex is very acuminate or cuspidate-acuminate, and the base cordate

with rounded auricles, which often overlap or have their edges pushed upwards from their under sides being applied to each other; both sides are sparsely and somewhat roughly hairy, but the hairs are most abundant beneath; the margin is irregularly and obtusely sinuate-dentate, though much less marked on the entire leaves, and the lobed leaves have the tips of the lobes drawn out to a somewhat blunt point. In the axils of the basal veins on the under-surface of the leaf are seated large pallid glands. The colour of the leaf is dark bronzy-red on bronzy-green, with a purple tint, and red veins above, and entirely vinous-purple beneath. The Fig is stalked, subglobose, about half an inch in diameter, finely and densely pubescent, and of an ochreous colour, the mouth is slightly conical, and closed with purple scales; the peduncle is about one-third of an inch long, finely pubescent, with three or four small, oblong, obtuse, pubescent, reddish-brown bracteoles placed under the Fig. The flowers in the only Fig examined by me were all female, and alternately pedicellate and sessile, the sessile ones usually with four, and the stalked ones with five, linear-oblong purple perianth segments. The plant is a native of the Society Islands. *N. E. Brown, Herbarium, Kew.*

*ALBUCA (LEPTOSTYLA) ALLENÆ, Baker, n. sp.**

This is a fine new species of *Albuca*, which has just been flowered at Hildenley, and a plant sent to Kew by Sir C. W. Strickland. It comes from Zan-zibar, doubtless from the mountains of the interior, at the same height above sea-level, as the new *Kniphofia* I described a short time ago. It is interesting botanically, as being just half-way between a typical *Albuca* and a typical *Ornithogalum*. The stamens are just like those of an *Albuca* of the section *Pallastema*, but the style is not at all triquetrous, nor are the inner segments of the perianth connivent or appendiculate, with a gland at the tip. In general habit and the size and colour of the flowers it closely resembles *A. Wakefieldii*, Baker, in *Botanical Magazine*, t. 6429, which is identical with *A. Elwesii*, Regel, and which comes from the same region, I have named it *Allenæ* at the request of Sir Charles Strickland, after the lady from whom he has received this and several other interesting plants.

Bulb globose, above 2 inches diameter; outer tunics pale brown, produced. Leaves about six, lanceolate, flaccid, bright green, glabrous, 1-1½ foot long, 1½-2 inches broad low down, with a narrow diaphanous entire edge. Peduncle terete, green, stiffly erect, 3-4 feet long. Inflorescence a lax narrow raceme a foot long; pedicels ascending, the lower under an inch long; bracts small, brownish linear from a deltoid base. Perianth oblong, greenish-white, under an inch long; inner segments oblong, opening out when the flower expands; outer, oblong-lanceolate. Stamens nearly as long as the segments; filaments linear, sharply constricted above a quadrate base; anthers oblong, yellow, versatile, one-sixth of an inch long. Ovary trigonous; style subulate, ½ inch long, reaching to the tip of the segments; stigma capitate. Ovules many in a cell, superposed, *J. G. Baker.*

CATASETUM PULCHRUM, N. E. Brown.†

The species of *Catasetum* are, as a rule, more curious than beautiful, but of late MM. Linden, of Brussels (Société anonyme, "l'Horticulture Internationale"), have been the fortunate introducers of several rather striking species, notably *C. tigrinum*,

* *Albuca (Leptostyla) Allenæ*, Baker, n. sp.—Bulbo globooso magno; foliis productis 6-8 lanceolatis flaccidis glabris viridibus pedalis vel sesquipedalibus; pedunculo valido erecto 3-4 pedali; racemo laxo angusto, pedicellis ascenduntibus; bracteis parvis acuminatis; perianthio albo-viridis segmentis ascenduntibus, exterioribus oblongo-lanceolatis interioribus oblongis haud conniventibus; staminibus perianthio vix brevioribus, filamentis supra basin latam coarctatis; stylo subulato elongato. *J. G. Baker.*

† *Catasetum pulchrum*.—Bulbis fusiformibus, 4-6 poll. longis, leviter sulcatis; racemo paucifloro, deflexo; sepalis petalisque ellipticis, acutis, patentibus, viridibus, rubro-brunneis transverse zonatis; labello saccato apice breviter tridentato, aurantiaco. Ex icone tantum descripsi. Habitat Brazil. *E. N. Brown.*

and the superb *C. Bungeorothii*, which is the finest known member of this interesting genus. The present novelty has recently been introduced from Brazil by E. S. Rand, Esq., and sent to MM. Linden. It is a very pretty and distinct species, and one that is likely to become a desirable plant. It is of dwarfer habit than many of the species, and has short racemes which curve downwards and bear four or five flowers, which are about 1½ inch in expanse. The sepals and petals are broad, elliptic acute, and widely spreading. They are of a light green, marked with several transverse bars of a chocolate colour. The lip is saccate, with an oblong mouth, entire on the margin and shortly three-toothed at the apex. The colour is orange-yellow. It would be interesting to know what the other sexual forms of this species are like, though possibly they may be less ornamental than the form here described. [From an inspection of the drawings only.] *N. E. Brown.*

USEFUL INFORMATION.

THE subjoined lists were intended for publication in the Sheet Almanac given in the present issue, but considerations of space led to their exclusion and to their publication in the present place:—

GOVERNMENT OFFICES, &c.

Privy Council, Agricultural Department, Whitehall.—Vice-President, Lord John Manners.

Board of Trade, Whitehall.—Vice-President, Lord Stanley of Preston; Secretary, H. G. Calcraft, Esq.

Emigration Information Office, 31, Broadway, Westminster, S.W.

Normal School of Science, South Kensington.—Professors, Botany, D. H. Scott; Agriculture, J. Wrightson.

Science and Art Department, South Kensington.—Secretary, Colonel Donnelly.

School of Forestry (India), Cooper's Hill, Staines.—Professor of Botany, Marshall Ward.

Woods, Forests, and Land Revenues, 1 and 2, Whitehall Place.—Principal Clerk, John Russell Sowray.

Natural History, Museum, Cromwell Road, S.W.—Keeper of Botany, Wm. Carruthers, F.R.S.

Works and Public Buildings, 12, Whitehall Place.—First Commissioner, Right Hon. David Robert Plunket, M.P.

ROYAL BOTANIC GARDENS, KEW.

Director, W. T. Thiselton Dyer, F.R.S., C.M.G.

Assistant-Director, D. Morris, M.A., F.L.S.

Keeper of Herbarium and Library, Professor Oliver, F.R.S.

Principal Assistant, J. G. Baker, F.R.S.

Mycologist, Dr. M. C. Cooke, M.A.

Assistant for India, W. B. Hemsley, A.L.S.

Curator of Museums, J. R. Jackson, A.L.S.

Curator of Gardens, George Nicholson.

Assistant Curator, William Watson.

ROYAL PARKS AND PLEASURE GARDENS.

St. James's, Green, and Hyde Parks.—Ranger, H.R.H. the Duke of Cambridge; Superintendent of Works, William Browne.

Richmond.—Ranger, H.R.H. the Duke of Cambridge; Deputy ditto, Major-General T. H. Clifton; Keeper, J. W. Jordan.

Greenwich and Victoria.—Superintendent, J. T. Gibbon.

Bushey.—Keeper, C. Dann.

Hampton Court.—Keeper, G. T. Sawyer; Pleasure Gardens—Superintendent, A. Graham.

Regent's.—Superintendent, C. Jordan.

Battersea and Kennington.—Superintendent, A. Roger.

Windsor.—Ranger, H.R.H. Prince Christian; Deputy ditto, Captain Walter Campbell; Bailiff, John Peel.

New Forest.—Official Verderer, Rt. Hon. George Sclater Booth, M.P.

New Forest, Alice Holt, Bere, Parkhurst, and Woolmer.—Deputy Surveyor, Hon. Gerald W. Lascelles.

Forest of Dean.—Gaveller, George Culley; Deputy ditto, Thomas Foster Brown; Deputy Surveyor, Sir J. Campbell; Assistant, J. Ward.

BOOKS.

A SELECT List of Books useful for Young Gardeners and Amateurs:—

BOTANICAL BOOKS.

Botany, London Science Class Book. By Dr. McNab. (Longmans.)

Botany for Beginners. By M. T. Masters, F.R.S. (Bradbury, Agnew, & Co.)

British Flora, Handbook of. By G. Bentham, F.R.S., (L. Reeve & Co.)

Elementary Course of Botany, Henfrey. Edited by M. T. Masters, F.R.S., and A. W. Bennett. (Van Voorst.)

Lessons in Elementary Botany. By Oliver. (Macmillan.)

Plant Life. By M. T. Masters, F.R.S. (Bradbury, Agnew, & Co.)

Students' Flora of the British Isles. By Sir J. D. Hooker. (Macmillan.)

Treasury of Botany. Edited by J. Lindley and T. Moore. 2 vols. (Longmans.)

COTTAGE GARDENING.

Amateur Gardener's Calendar, Loudon's (F. Warne & Co.)

Garden Calendar. By T. W. Sanders. (London: (Adams & Co.)

Paxton's Calendar. (41, Wellington Street, Strand.)

DICTIONARIES, &c.

Alpine Flowers. By W. Robinson. (Murray.)

Cassell's Popular Gardening. (Cassell & Co.)

Dictionary of English Plant Names. By J. Britten and R. Holland. (Trübner & Co.)

Dictionary of Gardening. (Upcot Gill, 170, Strand.)

Encyclopædia of Plants. By Loudon. (Longmans.)

English Flower Garden. By W. Robinson. (Murray.)

Fruit Manual. By Dr. R. Hogg. (171, Fleet Street.)

DISEASES.

Diseases of Field and Garden Crops. By W. G. Smith. (London: Macmillan & Co.)

FORESTRY, TREES, &c.

Arboriculture. By J. Grigor. (Edinburgh: Edmonston & Douglas.)

Conifers, Manual of. (J. Veitch & Sons, Chelsea.)

Grafting and Budding. By C. Baltet. (London: Garden Office, 37, Southampton Street.)

Hardy Trees, Shrubs, and Herbaceous Plants, Handbook of. By Decaisne, Naudin, and Hemsley. (London: Longman, Green & Co.)

The Forester. By J. Brown. (Edinburgh and London: W. Blackwood & Sons.)

Tree Pruning. Des Cars. (Rider & Sons.)

FRUIT.

British Apples, Apple Congress Report. (Macmillan.)

Fruit Book, the Hardy. 2 vols. By D. T. Fish. (London: Bazaar Office, 170, Strand.)

Fruit Culture under Glass, Handybook of. By D. Thomson. (Edinburgh and London: W. Black & Sons.)

Fruit Farming for Profit. (G. Bunyard, Maidstone.)

Fruit Garden, the Miniature. By T. Rivers. (Longmans.)

Fruit Trees. By M. De Breuil. (London: Lockwood & Co.)

Orchard House. By T. Rivers. (Longmans.)

Pear Congress Report. (Royal Horticultural Society.) (Macmillan.)

Pine-apple, Culture of the. By D. Thomson. (Edinburgh and London: W. Blackwood & Sons.)

Strawberries. By W. Hinds. (Gardening World Office, 17, Catherine Street.)

Vines and Vine Culture. A. F. Barron, Sutton Court Road, Chiswick, W.

INSECTS.

Manual of Injurious Insects. By Miss E. A. Ormerod. (London: Swann, Sonnenschein & Co.)

LANDSCAPE GARDENING.

How to Lay out a Garden. By E. Kemp. (London: Bradbury, Agnew, & Co.)

MANURES.

Artificial Manures. By M. G. Ville. Translated by W. Crookes. (London: Longmans, Green & Co.)

PLANTS, FLOWERS, &c.

Bulbs and Bulb Culture. 2 vols. By D. T. Fish. (London: Bazaar Office, 170, Strand.)

Carnations and Picotees. By E. S. Dodwell. (Groombridge.)

Carpet-Bedding at Hampton Court. By A. Graham. (Hampton Court.)

The Chrysanthemum. F. W. Burbidge. Garden Office, 37, Southampton Street, Strand.)

Chrysanthemums. By Molyneux. (London: 171, Fleet Street.)

Chrysanthemums. National Society's Catalogue. (E. W. Allen, Ave Maria Lane.)

The Clematis as a Garden Flower. By Moore & Jackman. (Woking Nursery, Surrey: Jackman & Son.)

Ferns, Select. (B. S. Williams, Holloway.)

Florists' Flowers, Hardy, their Cultivation and Management. J. Douglas.

Flower Garden, The, Handybook of. By D. Thomson. (W. Blackwood & Sons.)

Gladiolus Cultivation. By Rev. H. H. D'Ombraim. (Reeve & Co.)

Greenhouse and Stove Plants. By T. Baines. (J. Murray.)

Greenhouse Management for Amateurs. By W. J. May. (Bazaar Office, 170, Strand, W.C.)

Hardy Herbaceous and Alpine Flowers, Handbook of. By W. Sutherland. (W. Blackwood & Sons.)

Ivy. By Shirley Hibberd. (E. W. Allen, Ave Maria Lane.)

Lily of the Valley Culture. By Jannock, King's Lynn.

Lilies and their Culture. By Dr. Wallace. (New Plant and Bulb Co., Lion Walk, Colchester.)

Narcissus, the, its History and Culture. By Burbidge and Baker. (London: Reeve & Co.)

Orchid Conference Report. (Royal Horticultural Society.)

Orchid Growers' Manual. (B. S. Williams, Holloway.)

Orchidaceous Plants, Manual of. (Veitch & Sons, Chelsea.)

Orchids, Cool. By F. W. Burbidge. (Chatto & Windus.)

Orchids, their Structure, History, and Culture. By L. Castle. (171, Fleet Street.)

Pimula Conference Report. (Royal Horticultural Society.)

Rose Garden. By W. Paul. (Waltham Cross.)

Roses, Book About. By Dean Hole. (Blackwood & Sons.)

Roses, List of. National Society's Catalogue. By Rev. H. H. D'Ombraim, Westwell Vicarage, Ashford, Kent.)

Roses for Amateurs. By Rev. H. H. D'Ombraim. (Gill, 170, Strand.)

Tobacco Culture. By E. J. Beale. (Carter & Co., Holborn.)

Willow, Cultivation of. By Sealing. (Kent & Co.)

PASTURE LAND.

Permanent and Temporary Pastures. By M. H. Sutton. (Hamilton, Adams & Co.)

VEGETABLES, &c.

Asparagus, Culture of. By W. Earley. (Bradbury, Agnew, & Co.)

Cucumbers and Melons. By W. J. May. (170, Strand, W.C.)

Kitchen and Market Garden. (Macmillan.)

Market Gardening. London: C. W. Shaw, (37, Southampton Street.)

Market-gardening, Farm. By C. Whitehead. (Effingham Wilson.)

Mushrooms for the Million. By J. Wright. (*Journal of Horticulture* Office, 171, Fleet Street, E.C.)

Potatoes, How to Grow. By J. Piok (Lockwood & Co.)

Vegetable Culture. By Sutton & Sons. (Hamilton, Adams & Co.)

Vegetable and Fruit-farming. By C. Whitehead. (12, Hanover Square.)

Vegetable Garden. By Vilmorin. (Murray.)

Watercress, Culture of. By Shirley Hibberd. (4 and 5, Ave Maria Lane.)

MISCELLANEOUS.

Buildings, Horticultural. By F. A. Fawkes. (Swann, Sonnenschein & Co.)

Cultivated Plants, their Propagation and Improvement. By F. W. Burbidge. (W. Blackwood & Sons.)

Floriculture, Domestic, Window Gardening and Floral Decorations. By F. W. Burbidge. (W. Blackwood & Sons.)

Garden Receipts. Edited by C. W. Quin. (Macmillan & Co.)

Gardeners' Assistant. By R. Thompson. (Blackie & Sons.)

Gardening, Epitome of. Moore and Masters. (Adam Black & Co.)

Parks and Gardens of London. By N. Cole. (*Journal of Horticulture* Office, 171, Fleet Street.)

Sub-Tropical Cultivation. By R. C. Haldane. (Blackwood & Sons.)

Tropical Agriculture. By P. L. Simmonds. (Spon.)

GARDENING PERIODICALS.

1787—Botanical Magazine. Editor, Sir J. D. Hooker. Monthly. (L. Reeve & Co.)

1841—Gardeners' Chronicle. Friday. Editor, Dr. Masters, F.R.S. Publisher, W. Richards, 41, Wellington Street, Covent Garden, London, W.C.

1842—Gardener's Magazine. Friday. Editor, Shirley Hibberd, Esq. Publisher, W. H. L. Collingridge, 148, 149, Aldersgate Street, E.C.

1848—Journal of Horticulture. Thursday. Editor, Dr. Hogg, F.L.S. Publisher, E. H. May, 171, Fleet Street, London, E.C.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM VAR. FASTUOSUM.

A splendid variety, with deep rosy-lilac segments and a narrow tongue-shaped white lip, with a central blotch of yellow and a few purple spots. When Hartweg, and about the same time Linden, discovered *O. crispum* (Alexandrae), they could have had no idea of the enormous numbers that would eventually be cultivated. *Lindenia*, t. 115.

CATASETUM BUNGEROTHI VAR. ACRUM.

A variety with lemon-yellow flowers. This magnificent species must surely conquer the prejudice of amateurs, and induce them to cultivate the variety.

For six months in the year they require next to no care, being simply hung up in a moderately warm dry position after the flowering period (October) till about the middle of March, when they are placed in a wooden basket in a compost of fibrous peat and green sphagnum, and then placed in a warm damp house, when they speedily renew their growth and sometimes show their flowers within a month. *Lindenia*, t. 116.

ALANTHES GRANDIFLORA.

A beautiful Madagascar species, with oblong leaves in two rows, and slender flower-stalks, each nearly as long as the leaves. The individual flowers are about 5 inches in longest diameter, pure white, with sepals and petals broad at the base and tapering into long tails; the lip is bent abruptly in the middle, with a dilated basilar portion and an anterior broadly ovate lobe prolonged into a long process. The lip is provided at the base with a blunt spur, shorter than the flower segments. *Lindenia*, t. 109.

MASDEVALLIA MACGURRA.

A species with stalked, oblong leaves, tapering at the base, tall peduncles, nearly as long as the leaves and each bearing two flowers, each 9—10 inches in the longest diameter, with a short tube about three-quarters of an inch long, and three long slender tails, directed, one vertically upwards, the other two straight downwards. The colour is yellow, flushed and spotted with brown round the open throat, which latter is white. It is a native of New Granada, where it was discovered by Wallis, and introduced by him into M. Linden's establishment (*Lindenia*, t. 113), and originally described in our columns, 1874, i., p. 240.

CATTELEYA LABIATA VAR. AUTUMNALIS.

The autumn-flowering variety of *Cattleya labiata* is remarkable for the intensity of its colouring, its rarity, and the season of its flowering. The sepals are narrow and oblong, the side petals broadly ovate, obtuse, deep rose, the basal part of the lip upturned on each side, so as to form an imperfect tube, and an anterior roundish lobe of a rich purplish-crimson, with yellowish blotches on each side near the throat, and a few purplish stripes in the same place. *Cattleyas*, as the Editors of the *Lindenia* rightly say, justify the fancy of the amateurs for them, not only by reason of their dazzling beauty, but from the fact that some one or other of them may be had in bloom almost throughout the year: thus, in spring come those of the Triana section, quadricolor, bogotensis, and choconensis. These are followed by the Mossies, then gigas, aurea, Gaskelliana, then Percivaliana. *C. magnifica* is not yet introduced. *Lindenia*, t. 112.

CYPRIPEDIUM IO X.

A hybrid between *C. Argus* and *C. Lawrenceanum*. Leaves marbled, dorsal sepal ovate, white with purple stripes, petals spreading, green at the base, purplish at the tips, and with deep brown hirsute spots at the edges; the lip is greenish suffused with purple. A coloured figure is given in the January number of the *Revue de l'Horticulture Belge*.

NOTICES OF BOOKS.

DAS PFLANZENPHYSIOLOGISCHE PRACTICUM.

By Dr. W. Detmer, Professor in the University of Jena. 1887. (Physiology of Plants, &c.) Williams & Norgate.

There are two points about the experimental science of the physiology of plants which should be borne in mind by those who teach it; in the first place, the apparatus needed to demonstrate most of the fundamental phenomenon is extremely simple; and in the second, the order in which the demonstrations are arranged is a matter of primary importance. It must be allowed by all readers that Dr. Detmer has at least not neglected the first of these points, for he has produced a book which is full of excellent descriptions of simple and efficient pieces of appa-

ratus designed to illustrate the chief facts known about the physiology of plants, and he never forgets that his science is an experimental one—a truth too much neglected in this country. With respect to the second point, however, we are not quite so fully in accord with the author. Of course, there is always in the arrangement of a series of studies something to be put down to the individuality of the teacher; but there is, again, much that is generally conceded, and we should suppose that the fundamental idea running through a course of experimental physiology should be progress from the less special to the more special phenomena. For instance, Dr. Detmer gives a chapter or section on "the formation of proteids in the plant," near the commencement of the book (p. 39); but the properties of proteids, and their re-actions, are not studied until we reach the middle of the work (p. 168); and again, a series of very elementary studies of the properties and structure of starch grains, are given at pp. 70—72, though the production of starch grains in the chlorophyll corpuscles is studied in the first section of the work. There are also several other cases of what looks to us like an inversion of the proper order of teaching, and we think the author has also unnecessarily entered into purely histological and anatomical details, e.g., the vascular bundle of Zea Mays, the structure of the endosperm of Wheat and Ricinus, &c. It seems to us that, on the one hand, the student who has not mastered these or equivalent exercises, is not properly prepared for the study of physiology proper; and, on the other hand, Dr. Detmer's short paragraphs on a few of these subjects are not calculated to replace the proper preliminary studies. To give an outline sketch of the plan:—The work is divided into two parts. Part I. deals with the "Physiology of Nutrition," Part II. with the "Physiology of Growth and of Irritability." Each part is further subdivided into sections, those in Part I. being devoted to (1) "The Nutritive Materials of Plants," (2) "The Molecular Forces of Plants," (3) "The Processes of Metabolism in the Vegetable Organism;" those in Part II. comprise "The Growth Movements of Plants," and "Movements of Irritability." Each of these five sections is then subdivided into what we may perhaps call chapters on Assimilation, the Origin of Proteids, the Ash-constituents, Organic Compounds as Nourishment for Plants, &c.; and under each of these headings are numbered paragraphs embracing the descriptions of apparatus and procedure in experiments.

We have scarcely anything but unqualified praise to bestow on the individual experiments, and we need say no more as to the arrangement.

A few words are called for as to the meanings of some of the titles to sections and chapters, however. What is the implication under the mysterious heading, "The molecular forces of plants"? We know it is a favourite German expression, but Dr. Detmer collects under this title so many and such various phenomena, that it leaves the reader in a maze of doubt as to the meaning. For instance, why is the subject of the absorption of minerals, &c., by the roots treated here, and that of the decomposition of nitrates in the plant under a totally different heading? Or, again, surely so far as the above title indicates, the absorption of gases is a subject as well qualified to be honoured under it as that of the absorption of water. And now a final grumble as to the literature. It would have been an intelligible position had the author assumed that there was no necessity to quote literature; having done so here and there, however, he lays himself open to the criticism that the citations are very incomplete and partial. For instance, no mention of Dr. Francis Darwin's elegant experiments on the transpiration current occurs, though the writer gives no better method. Knight's name is referred to in connection with the centrifugal machine; but no mention of Hales occurs when treating of root-pressure, &c. Bous-singault's name is mentioned in connection with the question of the relationship of atmospheric nitrogen to plants, but Messrs. Lawes and Gilbert's magnificent results are ignored; and although Sachs is quoted as using the lithium method for determining the rate

of the transpiration current, no notice appears of McNab. We are surprised to see no mention of Elvring's experiments on the conductivity of vascular bundles, or of Engelmann's fascinating bacteria test for oxygen. It will thus be seen that the book is not free from the charge of partiality, and it is at any rate in so far incomplete that no experiments on reproduction are given; but, worst of all, there is no index. The print is very clear, and the woodcuts numerous, sharp, and simple, and admirably chosen; a goodly number of the histological ones, however, are old friends to all who know Strasburger's *Botanische Practicum*.

ROSES.

THE FORCING OF THE MARECHAL NIEL ROSE.

This fine Rose is more easily excited by heat than almost any other, hence it is the earliest of all Roses in the open air, beating even the Gloire de Dijon by a fortnight or three weeks. Were it as thin and flimsy as Madame Falcot or Roses of that type, it would be still earlier in bloom. Our temperature in the open air is by no means exciting, but it suffices to unfold this Rose on sunny walls. Hence a range of temperature included between 50° and 65° is probably the most suitable for forcing it. The air should be dry rather than moist, and but little overhead syringing should be done early in the season. Keeping the fat buds wet is a sure recipe for disfiguring their crown or rotting their base. In bright weather a mere dewing over in the early morning and about 4 o'clock in the afternoon may be indulged in, but any overhead sprinkling beyond this should be avoided. Overwatering at the roots should also be guarded against, as well as the opposite extreme of excessive dryness.

Immediately after the blooming, too, when the fresh breaks are rushing forth, or current ones, relieved of the strain of the flowers, are being plumped up into vigorous maturity, the roots also need to be liberally supplied with food and drink, but during the blossoming a moderate water and food supply proves the most successful, and results in the fullest crop of the most perfect flowers. A free circulation of air is also one of the most vital conditions of success. At all times, when the external air exceeds 45° or 50°, the air may be admitted with tolerable freedom. During colder weather, a free circulation of the internal air of the Rose-house should be promoted by every available means, such as unequal distribution of heating surface, underground drains, dividing screens, and other causes of motion. That the air should be kept in motion is almost as essential to the full development of colour, as that the plants should be fully exposed to direct sunlight. And two of the most substantial benefits resulting from the forcing of the Maréchal Niel Rose on roof trellises are, that the plants are at once subjected to the maximum intensity of solar light and the maximum forces of atmospheric air in vigorous motion. And these two combined result in a vigour, finish, and intense glow of colour comparatively seldom reached in the open air.

Of course there are exceptions. Maréchal Niel may be hurried out of character or form by excessive heat, and the brilliant gold matured or blanched down into pale straw colour by excess of food or a paucity of light; but such samples are spoilt in the process of development, and are by no means fair illustrations of good forcing. It may also be added, as a warning against coddling treatment or any excess of heat, that the most brilliantly coloured and altogether most perfect Maréchal Niel Roses ever seen by the writer were grown in an unheated house, very openly glazed, in which any excess of heat was a physical impossibility. But this testimony to cool treatment reads rather like a bull in an article on the forcing of the Maréchal Niel Rose; I will therefore hasten to conclude with a few re-

marks on the forcing of the *Maréchal Niel* in pots. This has developed into almost a new form of *Rose* growing in pots. Visitors to nurseries have long been familiar with the requirements of pot-Vines, many thousand battalions strong, that fill perfect glass villages of pots and houses in many nursery gardens. These are struck from eyes early in the spring, and rushed up as rapidly and robustly as possible throughout the season to a height of from 6 to 10 feet high. No expense of time, labour, skill, manure, space, is spared to develop and mature these long Vine-rods; and all this is done to such good purpose that the canes of the current year are able to carry from four to six good bunches of Grapes to perfect maturity; the next after that, as a rule, the plants are thrown away. Now by substituting *Maréchal Niel* Rose for the Grape

but rather that of growing and blooming maiden plants only once.

These one-shooted, highly portable plants, grown in 10 or 12-inch or larger pots, are also admirably adapted for subjection to bottom-heat, which proves a most useful stimulus to the forcing of *Maréchal Niel* Roses, if not carried greatly beyond a temperature of 65°-70°. Plunged into fermenting materials, such as leaves and farmyard manure considerably ameliorated and sweetened down, it is astonishing how the roots run into new growth, and are quickened into almost unnatural activity and vigour. This speedily reacts on the tops, and one can almost see the Vine-stemmed Roses burst into leafage and bloom under such stimulating treatment. The plants have been formed on the principle of as much flowering force as possible within the smallest

of their plants, but rather to prevent any from despairing. But the *Maréchal Niel* well forced or grown under glass, or in the open either, is so magnificent, that no effort, nor skill, nor attention can be deemed excessive to produce it in perfection. Those Vine-stemmed plants, so admirably adapted for forcing, are equally useful for the furnishing of walls with flowering plants on the instant in situations where, from various causes, such as lack of depth, or mass, or suitability of root-runs, the plants cannot be permanently grown where wanted to bloom. By plunging the pots, mulching them with manure, feeding them with liquid-manure made from soot and guano in equal parts, such plants will furnish any bare building with a magnificent golden harvest without further preparation or trouble. They would do better still if turned out of the pots into a nice bed of rich

FIG. 1.—STACHYS TUBRIFERA: A CHINESE EDIBLE TUBER. (SEE P. 16.)

Vine this system of propagation and treatment describes exactly the newest and most improved system of forcing the *Maréchal Niel* Rose in pots. Thousands and tens of thousands of this Rose are thus propagated either from eyes or worked on rootstocks, grown on, matured, flowered, and afterwards thrown away or planted out for general furnishing.

These long Canes may be trained up roof trellises of houses or pits, or grown on stages or floors of light and airy houses, forced into bloom throughout the whole or a portion of their length as is most convenient or most profitable. So far as their forcing is concerned, they are treated as annuals, and done away with so soon as their first harvest of flowers is gathered.

By cutting back at once near to the base of the scion or rootstock, a second flowering shoot might be produced for the following season; but this is not the course recommended here and now,

possible area and the least time, and they respond with showers of gold, while those grown on less intense and concentrated methods have hardly broken into their first leaflets.

All this, however, must not be allowed to convey the impression that no considerable success in forcing the *Maréchal* is possible on more ordinary modes of culture. On the contrary, no variety of Rose will yield better results with less care. Hence standards on their own roots and on various stocks, will yield good harvests of bloom in pots under glass. The writer has seen starved looking and stunted *Maréchals*, and in one special case a venerable scrambling weeping bush yield a magnificent harvest of bloom in a vinery, put under a dense canopy of Vines—about the most unsuitable place possible. This is not recorded for the sake of making cultivators careless or indifferent about the character or strength

compost or manure. By such means those who can command a moderate sum of money may post *Maréchal Niel* on bare walls, balconies, against our houses or offices, in streets, and the most unlikely and impossible places, and yet cut golden Roses in quantity and of creditable quality. The cost of maiden plants annually will be as nothing, and the pleasure of seeing their beauty and sharing their sweetness, when all else is hard, utilitarian, bald, and bare, if not absolutely vile, is very great. *Rosa*.

GARDENING UNDER DIFFICULTIES.—The Superintendent of the garden of His Highness the Maharana of Oodeypore (Central India), reports that a large number of shrubs and trees have been "completely destroyed by a large gang of black-faced monkeys through wanton mischief." The Superintendent further reports that he is "glad to hear that the chief of the gang was captured and transported to Chittore."

PLANT NOTES.

OXERA PULCHELLA.

Amongst the many rare and beautiful plants in Sir George McLeay's collection, the above stands out conspicuous. At the time of my visit (December 28) this plant was coming into bloom, and when more generally known will become a favourite with lovers of handsome climbing plants. It is of easy culture, requiring the temperature of the stove or intermediate-house, it grows freely in a mixture of loam and sand, with a little peat and charcoal added and is readily propagated from cuttings. It is a native of New Caledonia. The flowers are nearly white, and are produced in profusion. The plant was figured in the *Botanical Magazine*, t. 6938, where we are told that the genus is closely allied to *Clerodendron*, of the climbing species of which it has the habit, also in its flowers when in a bud state; in fact, when we first saw it in that stage it looked remarkably like *C. Balfourii*, but it differs in having only two stamens, and a deeply divided drupe. *W. B.*

TULIPA AUSTRALIS.

A yellow-flowered species suitable for rockwork. It is known also as *T. Celsiana* and *T. Breyniana* (*Botanical Magazine*, t. 717). It is very like *T. silvestris*, which in this country has the defect of not opening well. *T. australis* is figured in the *Garden* for December 17.

THEOPHRASTA JUSSIEI.

Some weeks ago there was an article in the *Gardeners' Chronicle* relating to this plant by Mr. Nicholson, of the Royal Gardens, Kew, stating on my authority that the plant at Kew was the only one known to be in this country, or even in Europe. I formed this opinion on many years' correspondence with curators and nurserymen, both in this country and on the Continent, and on my never having seen the name in any garden or nurseryman's catalogue; but in this I find I am mistaken, for in reply to Mr. Nicholson's notice, Mr. Burbidge, of the College Botanic Garden, Dublin, says it is not such a rare plant as Mr. Nicholson states, as there is a plant in the College Botanic Garden, one at Glasnevin, and one he has heard of at Cork. I begin first with the history of the Kew plant, which is this, as told by Mr. Lambert, who was a great introducer of rare plants towards the end of the last and early years of the present century:—In 1818 it was sent to him by Dr. Hamilton from San Domingo, and for care it was placed in the nursery of Mr. Colville, King's Road, Chelsea, whose property it ultimately became. On the breaking up of that nursery in 1834 the plants were disposed of by public sale, and I was instructed by Mr. Aiton (then Director of the Royal Gardens) to endeavour to purchase certain rare plants for Kew. This I did, *Theophrasta Jussiei* being one which was knocked down to me for £4, being the highest price realised for a single plant at the sale; it was then about 3 feet high—a single-stemmed plant, with a crown of Holly-like leaves. It has now, Mr. Nicholson informs me, a clear stem of 12 feet, thus showing that its rate of growth is about 2 inches in a year, which is verified by the spaces between the scar marks of the rings of fallen leaves.

With regard to the size of the Irish plants Mr. Burbidge informs me that the plant in the College garden is 5 feet 10 inches high; he does not give the height of the clear stem, but we presume it to be about 4½ feet; to attain this at the same rate of growth as the Kew plant it must have been a young plant about the year 1860. With regard to the Glasnevin plant, it is said to have a clear stem of 4 feet 9 inches; which at the same rate of growth shows that these two plants must have been received at the respective gardens about the same time, but neither Mr. Moore nor Mr. Burbidge can give any historical account of their introduction; but this is not all, for Mr. Moore informs me that about

twenty years ago there was a fine plant of *Theophrasta Jussiei* in the Glasnevin Garden about 15 feet high, but contingent on its removal to a larger house, which did not suit it, it died. To have been 15 feet high twenty years ago (say 1866), with the same rate of growth as the Kew plant, its introduction must have been at the end of the last century—if then introduced as a young plant.

I have now to speak of a distinct plant which for several years bore the name of *Theophrasta Jussiei* in gardens. In 1819 Dr. Wallich sent from the Calcutta Garden a case of living plants to the Edinburgh Botanic Garden; in it there was a pretty plant about 6 inches high, with Holly-like leaves; it was not named. On my coming to Kew I found that he had sent plants here, which had been propagated, and bore the name of *Theophrasta Jussiei*. I presume that it received this name on account of its likeness to the plant of *Theophrasta* in Colville's nursery, and it was considered a plant of fame, and worthy of being stolen. It, however, lost its fame consequent on its having flowered in the Comtesse des Vandes' garden at Bayswater, when Dr. Lindley figured and described the plant in the *Botanical Register* as a new genus under the name of *Brexia madagascariensis*, being the type of a small family, *Brexiaceae*.

My reason for inserting this in the *Gardeners' Chronicle* is to bring it to the notice of your readers, in hopes that one of them may be able to throw some light on the introduction of the plants of *Theophrasta* in the Irish gardens, as also on the plant seen by Mr. Watson in the Rotterdam Garden, which, he says, is equal to the Kew plant in height. *J. Smith, Ex-Curator, Royal Gardens, Kew.*

"BOLDA" (BOLDOA FRAGRANS).

A plant of this interesting shrub is now in flower in the cool Economic-house at Kew. The leaves are 1½ inch long, ovate, deep green, and almost stalkless; they are also very aromatic when bruised, the odour being something like that of the Allspice tree. The flowers are in small terminal racemes on the small twiggy branches, and they may be compared to bunches of May blossoms. Each flower is composed of a row of white strap-shaped, twisted petals, a quarter of an inch long, and the centre is occupied by a cluster of stamens with yellow anthers, the plant under notice being a male. The economic value of this plant is chiefly in the medicinal property of its leaves, which are used against indigestion. The bark also is useful for tanning, and the fruits, which are about the size of Haws, are eaten in Chili, where this species is a native. In the *Genera Plantarum* this plant is placed under the genus *Peumus*. It is figured in the *Botanical Register*, 1845, t. 57, *W.*

HOYA BELLA.

This is one of our neatest stove plants, but seldom seen in collections. It is an excellent subject for baskets, and is equally well grown as a plant trained as a balloon, a pyramid, or as a climber—a damp wall in the stove is well adapted; the beautiful corymbs of small waxy flowers possessing a pleasing effect in such a position. Cuttings taken off in late spring, put in a pot containing a compost of one part silver sand, the other fine broken peat, and placed in a handlight on a brisk bottom-heat, will strike readily. *G. H., Merton.*

COLONIAL NOTES.

THE BANANA TRADE, TRINIDAD.

Mr. HART, Superintendent of the Royal Botanic Gardens, Trinidad, has published a pamphlet advocating the culture of Bananas in that island for the New York market. Mr. Hart shows that the scheme is quite feasible, and that the variety to be grown is that known as Gros Michel. Jamaica in 1885 exported Bananas to the amount of £130,000, an amount still increasing; and there is no reason, according to Mr. Hart, why Trinidad should not share in the spoil. Mr. Hart looks to the United States to take as many Bananas as can be grown, and reads his fellow-countrymen a lesson in the following terms:—

"Throughout the American continent we find a readiness to adopt to certain uses whatever comes to hand which we do not find in older countries with more lengthy traditions. The Englishman, whether he calls himself Conservative, Liberal, Radical, or even Home-Ruler, is, and cannot help being, when at home, in most of his actions nothing else but a Conservative, and hence his general unwillingness to adopt new ideas and take up food-sources as quickly as the American. For these reasons it is doubtful, even if the difficulty of transit were overcome, whether the trade would prosper to the same extent and with the same rapidity as it has done in America."

While in the main we agree with Mr. Hart, nevertheless we believe that if the Trinidad planters could supply our markets with some of the finest flavoured varieties in place of the mawkish things we get now, there would spring up a demand even in conservative Britain. Many people also are unaware how greatly even ordinary Bananas are improved by stewing with syrup.

MONTREAL.

The twelfth annual report of the Montreal Horticultural Society has been published. It contains the reports of the practical discussions on fruits, which are so valuable a feature in Transatlantic societies. In the course of these, Mr. Gibbs alluded to the Russian varieties of Apple tried in Canada. Mr. Penhallo reports on the spot in Apple due to the fungus *Fusicladium* and other observers narrate their experiences in cultivation. Mr. Stevenson and Mr. Starr speak with pride, as well they may, of the magnificent display of fruit and other Canadian products at the Colonial Exhibition, and give some good advice as to marketing, packing and shipping only the best fruit. A translation of Dr. Albert Regel's paper on the fruits of Turkestan is also given. Some of the Central Asiatic Vines are distinguished for early ripening; thus, in Tashkend, the Grapes ripen in June, in Darvas at the end of July. These Grapes would be worth experimenting on could they be obtained, either for cross-breeding or grafting. Apricots, Cherries, Peaches, and Nectarines, are very abundant, and of excellent quality. Melons are abundant, but the few that have been tried in this country are of indifferent flavour.

HALIFAX, NOVA SCOTIA.

Dr. Lawson reports that the Apple crop in Annapolis and Cornwallis is this year deficient in quantity. Potatoes also are deficient and of bad quality from the long drought. In the United States also the Potato crop is deficient.

NATAL BOTANIC GARDENS.

White ants are no respecters even of Eucalypti. Mr. Medley Wood records in his annual report for 1886, which has only now reached us, that out of fifty-eight plants belonging to twenty-two species only eighteen plants remain. Roses have not been molested, but the immunity has only been obtained by growing the Roses in tubs placed upon inverted glass bottles. The wooden seats in the garden also offer irresistible temptations to the ants.

PLANTS AND THEIR CULTURE.

As we have now entered on another year, possibly no more fitting time than the present will be found in which to take a brief retrospect of our experiences in the culture of plants under glass during the year which has just ended. In doing so, notwithstanding the success with which many of our efforts were crowned, some of us will, unfortunately, have to chronicle some failures more or less, and this, too, in spite of well laid plans and much consideration; but having noted the probable cause, it should be our aim this season to convert at least some of them into successes. It sometimes seems rather puzzling why a cultivator should succeed with a particular plant, when his, it may be almost next-door neighbour, attains but a very meagre degree of success; and this, too, after the most careful and unremitting attention on his part. Clearly there are some circumstances or conditions to which the plant cannot adapt itself. Now whether it be the comparative absence or excess of heat, light, moisture, or ventilation, this the cultivator ought to strive to find out. Old and experienced hands can very often tell from the general appearances of a plant what kind of treatment is likely to suit it; they know that a plant which

has leathery shining leaves will withstand a great amount of light, the same of thick fleshy leaves; besides, they would not suffer so much from any temporary want of water as would a plant with thin soft leaves, with very little stock of reserve materials to fall back on; or, again, gardeners would not heavily syringe hairy or woolly-leaved plants. These indications also afford a pretty good idea as to the plants' requirements in regard to water and atmospheric conditions. Of course in a glasshouse it is rather difficult to reproduce in our artificial way the conditions under which tropical plants luxuriate in their native habitats, yet the nearer we approach to natural conditions the more likely we are to succeed; therefore, in the culture of plants under glass, it is well to take into consideration the conditions under which they were found growing in their original home, and adopt them as a basis for our cultural operations, and, all other things being equal, success will follow.

To attain to any degree of excellence in growing plants cleanliness must prevail, for when they become infested with insects it is vain to look for satisfactory results. Perhaps no more favourable time can be found than the present in which to give the plants and houses a general overhaul, and doing so at this season of the year has several advantages; inasmuch as in the majority of cases there is less pressure of work than later in the season, so that the work can be done in a systematic manner; moreover, the leaves of many kinds of plants are in a matured state, and therefore less likely to be injured in the work of cleaning. In the case of deciduous plants cleaning at this time of the year is rendered comparatively sure and easy. Again, many plants are partially cut back at this time, while others may be more or less thinned out, such as many of the climbers. If this kind of work is to be effectual no half measures are of any use—every plant and every part of the house must be seen to. It is best to begin by washing the house, first with warm water in which a little soft-soap—or, better still, Calvert's 10 per cent. carbolic soft-soap—has been dissolved, moving the plants to one side as the washing proceeds, so that when you get to the end of the house there will be a small space clear of plants. This space ought next to be thoroughly cleaned, including the shingle or other material which may be used for covering the stages or tables. Next see that the plants are clean before they are put back into their places. Having tried many insecticides it is but fair to say that I found most of them do all that they claimed to do, that is, if they are applied according to the directions given with them; but of recent years I have all but given them up, relying chiefly on clean water, which I find, if applied with sufficient force and persistence, is by far the least injurious, and most effective of all the insecticides I have tried.

Allamandas.—The present is a good time to prune back large plants which have been resting during the winter, and if they are growing in large tubs or pots, it may not be necessary to repot them if the drainage be good, for although they require a liberal allowance of water when growing, it must not become stagnant in the soil, or the bad effects will soon become apparent by the leaves beginning to droop and turn yellow. If they are not to be potted, scrape off as much as possible of the soil from the surface, and top-dress with manure—either well-rotted yard-manure, or some of the prepared fertilisers. Those which require potting had better be left until they break away, after being pruned. A moderately stiff loam, with sufficient sand to keep it porous, a small quantity of leaf soil, and a pinch of some concentrated manure is a soil which will afford good results. Do not give peat if it can be avoided. *Allamandas* enjoy a high temperature—75° at night, and full exposure to the sun. If the space at command is limited, and larger specimens cannot be accommodated, take pieces of the ripened wood, about three joints long—or the points of the shoots may be taken—insert them at once singly in small pots, and place in the propagating frame or house; if all goes well they will root in about a month, then gradually inure them to the atmosphere of the house. Shift them into 4-inch, and later into 6 or 7-inch pots, using the soil recommended above. Do not let more than two or three shoots develop, and usually once pinching will be found sufficient: those cuttings from the ripened wood rarely require any pinching. Grown on in this way, with plenty of heat and full exposure to the sun, they begin to flower, when about 3 feet high, generally in June (that is, if the cuttings are put in at once), and continue flowering up to Christmas, if occasionally supplied with liquid manure or top-dressed. In

potting, make the soil quite firm, indeed they can hardly be too firmly potted. The chief advantages of this system are, that large quantities of this charming flower may be produced without being encumbered with large plants or having large houses. The best species for this purpose are *A. cathartica*, light yellow, with a rather small undulated limb to the corolla; *A. nobilis*, a fine large flower, yellow, rather darker shaded in the throat; *A. Schottii*, a magnificent species, also with yellow flowers, but the throat is beautifully marked with brown; *A. grandiflora* is a very fine species, and which apparently does best when grafted on some of the stronger growing sorts. *F. Ross, Pendell Court Gardens, Blotchingly.*

THE HARDY FRUIT GARDEN.

PRUNING.—The remainder of the pruning of all kinds of fruit trees should be hastened on every favourable opportunity, so as to bring it to a close as soon as possible.

Nailing and Training.—The same remark also applies to the nailing and training of wall trees, which should be proceeded with without delay, beginning with Plums and Pears first, following with Morello Cherries, red and white Currants (when grown on walls), and Apricots, leaving the Peach and Nectarine trees till last. Here we always make a point of having Apricot trees nailed as early as possible, so that the trees can be protected should severe weather set in, the buds being liable to injury after the early part of January. Three-fourths of the buds on the Apricot trees were killed here two years ago in the early part of that month. After Morello Cherries are nailed the trees and walls should be subjected to a good washing of soapy water, forcibly applied by means of the garden engine or syringe, choosing a mild morning for the operation.

Manuring.—Cordon, pyramid, and bush Pears on the Quince, and Apples on the Paradise stock, which bore heavy crops last season, will be greatly benefited by a good mulching of half-rotten manure. Strawberry borders and beds that have been made a considerable time may, after being hoed and cleared of weeds, receive a liberal dressing of manure placed between the rows, which should be spread but should not be dug in, as by so doing a great number of the roots near the surface are destroyed. Raspberries and black Currants should also receive a good dressing of manure, old hotbed material being a capital dressing for Raspberries, and for black Currants nothing is better than long stable manure.

Insects.—Now is a good time for dressing with petroleum emulsion any Pear trees infested with scale. To make the latter, put 1 pint of petroleum in a bucket, over which pour 3 pints of boiling water, then take a syringe, and by its forcible use mix the two ingredients together for about ten minutes. The liquid will then have the appearance of cream, and should be allowed to cool before being used. This, if carefully applied to the stem and branches, with a brush, taking care not to touch the buds, is the most efficacious remedy that I know of for scale. It is also equally useful for dressing Apple trees infested with American blight, but on no account should it be used unless the trees are quite at rest. *A. Ward, Stoke Edith Gardens, Hereford.*

FRUITS UNDER GLASS.

THE PINERY.—**Fruiters.**—Pines which are swelling off their fruit must not receive too much water at the root, else they are liable to turn black in the centre. Maintain a moist growing atmosphere by sprinkling the paths and surface of the bed. Do not syringe the plants if you would avoid too large a development of crown. In mild weather the night temperature may range to 70°, and in the case of hard frost and wind to 65°. Where early Pines are a desideratum no time should now be lost in getting a few Queens on the way; but before starting them thoroughly clean and paint, if necessary, a division of the Pine-stove for their reception, and if the bottom-heat be dependent upon tan or leaves, it will be necessary to add some fresh material to produce the requisite degree of bottom-heat; but where hot-water pipes are in use this will not be necessary. The best plan is to plunge empty pots the same size as the plants occupy, this will allow of the plunging material

being made of more uniform firmness and ensure a more level surface; there is less likelihood of the leaves of the plants sustaining injury, all that is necessary being the removal of the pot and the substitution of the one containing the plant. In making a selection from the stock of Queens, choose those which matured their growth early, which are thickest at the collar, open in the centre, and have the greatest number of short leaves. These are the likeliest to show fruit without making growth. Remove a little of the old soil from the top of the ball and replace with loam containing a moderate dash of soot and Thomson's Vine Manure, ramming the soil moderately firm; give a good watering with clear water at a temperature of 85°, sufficient to moisten the whole ball; let the bottom-heat be kept as near 85° as possible; if it exceeds 95°, the pots should be shaken to allow the surplus heat to escape at the side of the pot. The day temperature should be 70° in mild weather; when it reaches 75° with sun, a little air should be admitted: during cold stormy weather 5° less will be better. Avoid syringing the plants overhead, as all the water runs down the leaves into the centre of the plant. Sprinkle the paths, walls, and surface of the beds with a fine rose, and by preference use the evaporating troughs. The night temperature should be 65° in mild and 60° in stormy weather.

Succession Plants should be kept quiet for the present, 55° top and 75° bottom; and when hard firing becomes requisite, the plants may require watering—this should not be done indiscriminately, but each plant should be first examined. Suckers which have well filled their pots with roots must be guarded against over-dryness at the root, else they are almost certain to "bolt" when a rise of temperature is afforded them. *W. M. Baillie, Luton Hoo.*

THE KITCHEN GARDEN.

With the beginning of another year come the various seed catalogues, and upon the way in which the order for seeds is made out a great part of the success of the crops, &c., will depend, preference being given to approved kinds. Novelties when they appear in the lists should be dealt with in small quantities only at first, proving their merit or otherwise before sowing or planting much of them; the want of caution in this way having sometimes unpleasant results, the following selection can be relied on:—Broad Beans: Johnson's Wonderful, French Beans: Sir J. Paxton and Canadian Wonder, Runner Bean: Champion Scarlet. Beet: Pragnell's Exhibition, Dell's Crimson. Broccoli: Veitch's Self-protecting Autumn, Snow's Winter, Adams Early, Leamington, Carter's Champion, Victoria, Brussels Sprouts: Exhibition and Imported. Cauliflower: Early London, Asiatic, Eclipse, Autumn Giant. Cabbage: Ellam's Early, Mein's No. 1, Enfield Market, Chou de Burghley. Carrot: Scarlet Horn, Early Nantes, Matchless Scarlet. Celery: Sandringham White, Major Clarke's Red. Cucumber: Kollinson's Telegraph Improved. Leek: The Lyons. Cabbage Lettuce: Paris Market, Perfect Gem. Cos Lettuce: Alexandra White, Paris White, Bath Cos. Onion: White Spanish, Reading, James Keeping, Globe Tripoli, Zittauer, Danver's Yellow. Peas: Laxton's Earliest of All, Marvel, British Queen, Ne Plus Ultra, Walker's Perpetual, Sturdy, Parsnip: Student, Savoy: Universal. Turnip: Extra Early Milan, Early Snowball, Veitch's Red Globe, Chirk Castle. Tomato: President Cleveland, Gilbert's Surpass, Trophy. When reliance can be placed on the stocks of the above-named varieties of vegetable seeds, preference should be given them over ordinary varieties, as better produce may thus be obtained, and especially is this noticeable in Onions and some other root crops.

General Work.—As crops get cleared off the ground take advantage of frosty days to get manure wheeled on to the vacant quarter and spread it at once. Give Asparagus beds a good dressing of well rotted manure—from the cowyard if possible; look over stores of roots and remove all that are decaying; attend to Seakale and Rhubarb for forcing, and get succession lots covered up as may be required. Veitch's Self-protecting Broccoli should now be turning in, and it will be advisable to take up any that are showing heads, placing them in a pit or other place of protection. Give plenty of air on all favourable occasions to Cauliflowers and Lettuce in frames and under hand-glasses; and dust occasionally the soil with lime and soot if slugs are troublesome. *W. H. Divers, Ketton Hall.*

Advertisers are specially requested to note, that, under no circumstances whatever, can any particular position in the paper be guaranteed for advertisements occupying less space than an entire column.

SUBSCRIBERS TO

THE GARDENERS' CHRONICLE who experience any difficulty in obtaining their Copies regularly, are particularly requested to communicate with the Publisher (in cases of delay in the delivery by post, the cover should be forwarded with complaint).

W. RICHARDS, 41, Wellington Street, Strand, W.C.

GARDENERS' CHRONICLE OFFICE TELEGRAMS. NOTICE to Correspondents, Advertisers, Subscribers and others. The Registered Address for Foreign and Inland Telegrams is "GARDCHRON, LONDON."

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

- MONDAY, JAN. 9.—Chambre Syndicale of Ghent.
- TUESDAY, JAN. 10.—Royal Horticultural Society: Scientific, Fruit, and Floral Committees; also Special General Meeting.
- THURSDAY, JAN. 12.—Edinburgh Botanic Society.
- SATURDAY, JAN. 14.—Royal Botanic Society, Regent's Park: General Meeting.

SHOW.

- WEDNESDAY, JAN. 11.—National Chrysanthemum Society: Mid-winter Exhibition at Westminster (two days).

SALES.

- MONDAY, JAN. 9.—Importations of Lilies, &c., from Japan, at Stevens' Rooms.
- WEDNESDAY, JAN. 11.—Roses, Fruit Trees, Shrubs, Border Plants, Bulbs, &c., at Stevens' Rooms.
- WEDNESDAY, JAN. 11.—Lilium auratum and L. Krameri, Roses, &c., at Protheroe & Morris' Rooms.
- THURSDAY, JAN. 12.—Importations of Orchids from Mr. F. Sander, at Stevens' Rooms.
- FRIDAY, JAN. 13.—Imported and Established Orchids, at Protheroe & Morris' Rooms.
- SATURDAY, JAN. 14.—Roses, Fruit Trees, Shrubs, Border Plants, Bulbs, &c., at Stevens' Rooms.
- SATURDAY, JAN. 14.—Lilies, Roses, and other Plants, at Protheroe & Morris' Rooms.

A New Vegetable.

It rarely falls to our lot to have to chronicle the introduction of an absolutely new vegetable. New Peas—literally as like Peas from the same pod—new Potatos, new Cabbages, Tomatos, Onions—these there are by the score. Only a few of them, however, stand the trial of the test at Chiswick, where the synonyms imposed by gardeners and seedsmen are as ruthlessly cut down and referred to their proper places as are the like double names by the systematic botanist in preparing a monograph.

But now we have really a novelty to lay before our readers, and it is one which we venture to think is far from unpromising. The tubers which we figure at fig. 1, p. 13, were exhibited at the meeting of the Royal Horticultural Society, on December 13 last, by Mr. HASKINGS, gardener to Sir H. THOMPSON, Hnrstside, West Moulsey, and were obligingly communicated to us for the purpose of illustration.

The plant producing these tubers is a Labiate, and is said to be a species of *Stachys*, allied to the Woundwort of our hedges, but without the disagreeable odour; but as we have not seen flowers or seed-vessels, we do not know whether this is correct or not. At any rate, the plant goes for the present under the name of *Stachys tuberifera*, our excellent correspondent, M. NAUDIN, having bestowed this name upon it, to replace that of *Stachys affinis*, which is quite a different plant.

Our first knowledge of this vegetable was derived from a notice in the *Revue Horticole*, 1885, p. 236. According to this, the plant was introduced from China to the Société d'Acclimatation of Paris by Dr. BRETSCHNEIDEN, Physician to the Russian Embassy at Peking. M. NAUDIN, however, in his recently published *Manuel de l'Acclimateur* (1887), p. 507, speaks of it as coming from Japan, and probably also from China. Possibly it may be the same as *Stachys Sieboldi*, which we learn is cultivated in Japan under the name of "Chorogi," but of this we have no means of judging. Its culture in France is due to M. PAILLIEUX, who now grows it on a large scale for the Paris market, where it is known under the name of *Crosnes*, from the locality in which it is cultivated.

As will be seen from our illustration, the tubers, are borne at the ends of underground branches, or stolons, exactly as in the Potato. The tuber in this case is, in fact, the thickened extremity of an underground branch, and it is marked by buds, or eyes, at the nodes, as in the Potato. Those who know the Fir-Apple, or Asparagus-Potato, will recognise the similarity between that variety and the new-comer. These tubers are produced in great profusion, and though at present of small size, are doubtless capable of enlargement at the hands of the gardener, especially if seedling varieties can be obtained. Unlike the Potato, these tubers have a bud at the end of the tuber (terminal), and this curves upward to form the new shoot; hence the propagation of the plant is easily effected, and as each tuber consists of several internodes—that is, has several buds or eyes—we have no doubt whatever that they may be propagated by sets or cut tubers, as in the Potato.

The plant is alleged to be perfectly hardy and of the easiest possible culture. It will grow anywhere, on any ordinary soil, but like other plants it will no doubt repay a little attention in the way of trenching and manuring. Its defects at present are its small size, and the fact that the tubers do not keep well when lifted; but both these defects can be overcome or evaded. In point of flavour we have heard it compared to Salsafy, Jerusalem Artichokes, and to boiled Chestnuts. Our own taste would lead us to consider it as most nearly allied in point of flavour to the latter. M. CARRIÈRE publishes the following analysis, which shows that the plant is a valuable food agent:—

Starch	17.80
Albumen: (including 0.60 N.)	4.31
Fatty matters	0.55
Woody matters and cellulose	1.34
Mineral matters: (including 0.28 phosphoric acid)	1.81
Water	74.19
	100.00

M. CARRIÈRE, while admitting that the difficulty of preserving the tubers militates against them as a market-garden crop, points out that it is well suited for the domestic kitchen garden, where the tubers can be lifted in late autumn or winter and eaten in a fresh state, either boiled, fried like Salsafy, made into sauce, or cooked in a dozen other ways that any cook—especially a French one—will devise.

The microscopic examination that we have been able to make does not reveal so large a proportion of solid starch as the chemical analysis would lead us to expect. Probably the amylaceous element exists in some other form than starch, as is the case in the Jerusalem Artichoke. The mass of the tuber consists of polygonal cells, with thickened corners, minute granules

perhaps of inulin, a few oil globules, large granular nuclei, and very bright nucleoli. Pitted vessels, sieve-tubes, and other elements of a modified stem-structure, are clearly apparent.

We believe that this new vegetable will make its way, not perhaps as a staple article of food—its tubers are too small for that—but as a very acceptable change on the tables of the connoisseur.

Its complete hardiness and easy cultivation will, we should also expect, cause it to be considered a luxury by the poor.

ALTHOUGH the past year has not been marked by the introduction of any such wonderful things as *Vanda Sanderiana*, and a few others which the collectors' enterprise has recently introduced to us, there is evidence that the importer as well as the hybridist has been busily engaged, and that, too, with considerable success. The summer-flowering Begonias of LAING and CANNELL have given us many improvements with single and double, and the Messrs. VEITCH in their new race of Begonias of the "John Neal" type bid fair to give us much of the beauty of the summer flowering kinds on autumn and winter flowering plants. The Dahlia still meets the approbation of the Floral Committees, more especially in the single, decorative, and Cactus formed classes; and the Chrysanthemum is likely to become the popular flower, even if it is not already so.

ORCHID S.

We naturally turn first to these for novelties; so many hands are engaged in the furtherance of their interests in these days that they must necessarily give a supply of good things. Among these the plant of the year may be said to be *Odontoglossum Harryanum* (*Gardeners' Chronicle* p. 469, August 7, 1887), which was sent out by Messrs. JAMES VEITCH & SON, and quickly made plentiful by a fine importation of Messrs. F. SANDER & Co., the same taking place in the matter of that other lovely autumn and winter-flowering plant, *Cattleya Bowringiana* which gives a very welcome addition to the Orchid-houses in the dull season, with its bright rosy-crimson flowers. *Catasetum Bungeothii*, certificated to Baron SCHROEDER at the Royal Horticultural Society, with its massive sprays of clear white flowers, is certainly a grand novelty of the highest merit, and an opportune arrival, as it gives a fresh start to a genus hitherto considered to be only worth culture on account of the curious structure of their flowers (*Gardeners' Chronicle* (Supplement), January 29, 1887). *Cattleyas* receive a valuable reinforcement in the varieties of *C. labiata* Schrodere, on account of their delicately tinted and well-formed fragrant flowers being produced over a long period, but generally coming in between the *Trianes* and *Mendeliis*. *Cattleya labiata leucophaea*, certificated to F. G. TAUTZ, Esq., is a very fine plant, the sepals and petals delicately tinted with lavender, and the darker portion of the lip the nearest approach to dark blue of any *Cattleya*; unfortunately it has no chance of becoming plentiful.

The *Odontoglossums*, which have hitherto been so prolific in certificated new and fine varieties, have of course fallen off in the number worthy of being considered distinct enough to particularise. Of crispums, the Royal Horticultural Society's Floral Committee have during the year selected but two, both grand things, viz., THOMPSON'S variety, with grand flowers nearly 6 inches across, heavily spotted with brownish-red, and *O. c. leopardinum*, a very neat, handsome, and

distinct form, with flowers barred and blotched all over with crimson. It was certificated to H. M. POLLETT, Esq., of Bickley, the same gentleman also receiving a First-class Certificate for a fine violet-spotted *Odontoglossum Pescatorei*. *O. cambridgeanum* of R. J. MEASURES, Esq., is very distinct, its appearance being between *O. nevadense* and *O. Halli*; and *O. Jacombianum*, a grand dark crimson-spotted form of the *Ruckerianum* type, but with flowers more of the form of *O. crispum*. The white and new varieties of

broad, richly-coloured lip of this variety which makes it easy to distinguish, and as a rule its flower-spikes are much shorter than the type. Many of these forms of *Laelia* have been illustrated in our columns. Another pretty little novelty is the *Laelia Batemaniana* × of Messrs. VEITCH, for which Baron SCHRODER was awarded a First-class Certificate on July 12 last.

The hybrid *Cypripediums* are just now great favourites, and several new operators are making good practice with them, and notably Mr.

mitted to the scrutiny of the Floral Committee during this year. In imported species of *Cypripedium* we gain two grand things in the quaint and lovely *C. Sanderianum* of the St. Albans firm, and *C. præstans* of LINDEN, figured in our last issue, the latter being in appearance a curious compound of *C. hevigatum*, *C. Parishii*, and *C. Stonei*. It is a good and distinct plant.

Calanthes, although largely crossed by several, manage to pass but two, viz., the fine pure white *C. Halli* × of Mr. HALL, and the rich and glow-

FIG. 2.—ENTRANCE TO A "CHICK HOUSE" AT GANISH KIND, INDIA. (SEE P. 15.)

Laelia anceps, from which much was expected, have not proved disappointing. *L. a. Schroderae* is a charming flower with blush sepals and petals and finely coloured lip; *L. a. Sanderiana*, a grand white, near to *L. a. Dawsoniana*, and well worthy to keep it company; and *L. a. Stella*, a large pure white, with dark crimson lines in the lip. Among the coloured kinds the *L. anceps* "Morada," of the Liverpool Horticultural Company, gives varieties which beat *L. a. Barkeriana* and other vaunted fine forms easily; a few of them, which have been selected and named *L. a. grandiflora*, being superb in size, form, and colour. There is a peculiar character about the

NORMAN COOKSON and Mr. DREWETT O. DREWETT. Among the new kinds which have been prominent during last year may be mentioned *C. Measuresianum* ×, illustrated in the *Orchid Album*; *C. Marshallianum* ×, a great beauty, illustrated in the *Gardeners' Chronicle*, April 16, 1887, p. 513; *C. leucorrhodum* ×, a beautiful thing of the *Seduni* strain, certificated to the raisers, Messrs. VEITCH & SON; *C. plumerum* × and *C. alium* × of Mr. NORMAN COOKSON; *C. Io* × and *C. orphanorum* ×, certificated to F. G. TAUTZ, Esq. Many other grand hybrids have bloomed with Messrs. JAMES VEITCH & SON, and others, which will doubtless be sub-

ing crimson or blood-red *C. sanguinarium* × of Sir TREVOR LAWRENCE—both extremely handsome.

Among the other new certificated Orchids are the pretty terrestrial *Habenaria militaris*, with its leaves as pretty as those of an *Anætochilus*, and its fine soft vermilion flowers—Sir TREVOR LAWRENCE grows it freely; *Cologyne Dayana*, *Odontoglossum Schroderianum*, *Phalenopsis Harriete* of Messrs. JAMES VEITCH & SON, *Saccolabium Heathii* to Baron SCHRODER; the rich scarlet *Masdevallia Harryana lutea oculata* (TAUTZ), *M. H. grandis* (SANDER), and several other acceptable novelties, which make the year fruitful so far as new and good Orchids are con-

cerned; and beyond this there are several fine importations, such as *Cœlogyne Fostermanni* and *C. Sanderiana*, which have not yet been proved, but from which much is expected.

We must postpone till our next issue our comment upon other New Plants of the year.

OUR ALMANAC.—Owing to the restrictions imposed by the Post-Office authorities, as explained in a previous number, we have modified our Almanac, which is now issued as an ordinary Supplement on a separate sheet. In addition to the usual calendrical matter, the Almanac contains indications of the mean temperature as observed at Chiswick for a long series of years, notices of the meetings of the horticultural and botanical societies of the British Islands and of the *Chambre Syndicale* of Ghent. These notices are much fuller than usual, but many are of necessity omitted, as the arrangements are not yet made. On the reverse side of the Almanac will be found a variety of miscellaneous information likely to be useful to our readers, but as the space is so limited a good deal of similar information is given in the pages of our present issue. Next week we hope to publish a list of all the more important horticultural societies of the kingdom, with the names of their respective Secretaries.

"CHICK HOUSES."—We do not propose to revive the old controversy as to who was the originator of these structures in India; suffice it to say that they are light structures of Bamboo and lattice-work, designed to afford protection from the burning sun and fierce wind. These Betel or Chick houses are now in general use in India, and, as our illustration shows, are by no means unpicturesque. A similar cheap contrivance might readily be adopted in this country for Lilies, Ferns, Camellias, Rhododendrons, and other plants for which a little shelter, either permanent or temporary, is desirable. We have seen such constructions used with advantage in some of the Italian Botanic Gardens, as at Pisa. The illustration (fig. 2) shows a structure erected at Ganish Kind, by Mr. Woodrow.

M. MORREN'S LIBRARY.—We have received a copy of the catalogues of the botanical and horticultural library of the late Professor EDWARD MORREN. It comprises more than 7000 entries, exclusive of the works of the two MORRENS, which by some accident are omitted from the copy of the catalogue which has reached us. It is rather astonishing that the Belgian Government should not have secured so valuable a library. As it is, the works are to be sold separately on application to Mme. V. ED. MORREN, Boverie 1, Liège. This is one of the richest collections that has ever been offered.

GHENT QUINQUENNIAL, APRIL 19—24.—In addition to the numerous prizes offered for new plants, Orchids, Nepenthes, Anthuriums, Palms, Cycads, Ferns, Amaryllis, Hyacinths, Azaleas, Camellias, Rhododendrons, Conifers, &c., we understand that the Agricultural and Botanical Society of Ghent, under whose auspices these shows are held, has offered prizes for the following botanical subjects:—
1. A series of fifteen distinct fungi, dried or in fluid, and representing the principal genera of Hymenomyces. 2. A series of preparations showing the different stages of flowering, e.g., ripening of the anthers, of the stigma, self-fertilisation, &c., illustrated by six flowers, which are fertilised by insects. 3. A collection of preparations showing the course of the fibro-vascular bundles in twelve flowering plants belonging to different families, isolated leaves and fruits not considered. 4. A collection of flowers of ten different types of Orchids preserved in fluid. 5. A collection of preparations showing the nature and construction of the different forms of fruits or seed-vessels that occur in wild plants or in those commonly cultivated in gardens. Ordinary herbarium specimens are excluded from these five classes.

Microscopic preparations, &c.:—1. A series of preparations representing six stages in the development of the stem, and of the root of the same species of the flowering plant. 2. A series of twelve microscopic preparations showing the division of the cell and of the nucleus (karyokinesis) in two or three different species. 3. A series of microscopic and macroscopic preparations representing at least ten different stages in the evolution of a hymenomycetous fungus from the first germination of the spore to the complete development of the plant. Competitors should indicate on each specimen the most remarkable points of interest.

NEW GUINEA PLANTS.—Baron VON MUELLER writes:—"From a small collection of plants, obtained by Mr. SAYEN during the expedition of Mr. CUTHBERTSON to Mount Obree in New Guinea, it is demonstrated that *Araucaria*, *Agapanthus*, *Rhododendrons*, *Ardisias*, *Myrsine*, *Ixoras*, *Oldenlandias*, *Myrtus*, *Medinilla*, *Scutellaria*, *Bradleyas*, *Mollineda*, *Nephelepis*, *Elatostemma*, *Elatocarpus*, *Biophytum*, *Dendrobium*, *Sarcocilus*, and *Calamus*, are among the genera which are represented at elevations up to 8000 feet, that being the culminating height."

VELPLANTENKRING.—Under this title has been established at Antwerp a society for the promotion of the knowledge and cultivation of Cacti and other succulent plants. The Secretary is Mr. J. HAVERMANS, Rue Jésus, 46, Antwerp, and meetings are to be held on the last Sunday of every month, at 11 o'clock, at the Tivoli, Rue du Pélican, 82, Antwerp. The annual subscription is fixed at six francs, with an entrance fee of three francs.

OODEYPORE.—The Superintendent's report of the gardens of His Highness the Maharana of Oodeypore, for 1886-7, contains a record of satisfactory progress. Roseries, carriage-drives, and fountains, "Jubilee halls," and other constructions, have been inaugurated. The rainy season began in June, when nearly 4 inches fell. This was increased to 8 inches in July, and 15 inches in August, more than 8 inches having fallen in two days. In September 5 inches fell, and after that time but little fell. The total amount for the year was 33.7 inches—no very large amount in itself. A frost occurred in the nights of the 16th and 17th of February, which did much damage. Potatoes do not flourish at Oodeypore; none of them were as large as a fowl's egg, and they had "a wildish taste." It is curious to read with this that the *Victoria Regia* flourishes in any lake or tank. By the way, the flowers are noted as opening at about 5 o'clock in the afternoon.

GERMINATION OF THE BRAZIL-NUT.—Most of our readers are familiar with the three-sided toothsome nut, and some perhaps have seen the hard, woody, globular case in which they are contained. The tree is native in the forests of Guiana and Brazil, and it has been an object with the authorities at Kew to introduce so valuable a tree into North Australia and other tropical colonies. It is recommended in the *Kew Bulletin* that the fresh seeds which arrive here in June should be sent in a box packed in cocoa-nut fibre or peat. On arrival the seeds should be soaked, the outer shell carefully removed, and the kernels sown in ordinary nursery beds. The germination of the seeds of this tree, *Bertholletia excelsa*, in the wild state, while enclosed in the wonderfully strong fruit-case, was long involved in obscurity. The hard, woody shell, useful as a protection against monkeys, seemed to offer a powerful obstacle to the germination of the contained seeds. Mr. BANNISTER BROWN, in the *Kew Bulletin*, describes the process as follows:—"In each fruit-case or pericarp, when lying on the ground, there is a small hole at the point at which it was attached to the stalk. Through this, after the fruit has been lying for some months in a moist situation, the shoot, produced by one of the germinating seeds, is able to effect an exit. When this is done, it gradually increases in size, but still uses the fruit-

case, which indeed protects its roots and serves all the purposes of a natural pot. The other seeds, unable to find outlet for their sprouts to reach the light and air, ultimately perish, and their remains probably go to nourish the solitary plant which is destined to represent the family. This latter, when it has grown to a certain size, bursts the shell in which its roots have hitherto been confined, and grows up into a tree." The gardener by cracking the shells, interferes greatly with this very Malthusian tendency on the part of the natural tree.

SMITHSONIAN INSTITUTION.—At a special meeting of the Board of Regents of the Smithsonian Institution Professor SAMUEL PIERPONT LANOLEY, LL.D., was duly elected (on November 18) Secretary of the Smithsonian Institution, Washington, to succeed the late Professor SPENCER F. BAIRD.

ORANGE CULTURE.—We learn that Mr. A. DIXON, of Cherkley Court, Leatherhead, has two Orange trees, each bearing more than 200 fruits. His Citrons usually produce fifty to sixty fruits annually in January.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The annual friendly dinner of the members of this Institution and their friends will take place after the General Meeting on Friday, January 13, at SIMPSON'S, 101, Strand, upon which occasion the Right Hon. Sir ROBERT PEEL, Bart., has promised to preside. The dinner will be upon table at 6 o'clock precisely.

FORMATION OF STARCH BY PLANTS.—Experiments have recently been conducted at the School of Agriculture, Canterbury, New Zealand, by Professors W. E. IVEY and G. GRAY, with a view to determine the formation of starch by plants. It has long been known that starch is formed either in chlorophyll granules or in starch-forming corpuscles, which ultimately become converted into chlorophyll granules, but up to the present little has been done towards ascertaining the rate of formation and dispersion. Accordingly a series of experiments were made to determine the rate at which starch is formed in the leaves of Peas, Beans, and Wheat, and up to date the following results have been obtained:—Starch is least plentiful in leaves collected in early morning, more plentiful in those collected late in the afternoon, but before evening. The degree of sunshine has a direct effect on the rate of starch-formation; in continuous cloudy weather starch is formed by plants but very slowly. This result was brought out in a striking manner. During some very cloudy weather, plant leaves collected before 9 o'clock A.M. exhibited but small quantities of starch, except on two occasions, when they had been under the action of direct sunshine; in those instances starch was proved to exist in large quantities. Determinations have not yet been made in leaves collected during absolute darkness.

REINWARDTIA TETRAGYNA.—The *Revue de l'Horticulture Belge* for the present month opens with a coloured plate of this pretty old warm greenhouse plant, which has well-nigh dropped out of remembrance, but whose many good qualities should have ensured it a better fate. It flowers at this season of the year, is attractive-looking, easily grown, and easily propagated. The plant is so near to *Linum* that it seems a pity to have ever separated it from that genus.

THEORY AND PRACTICE.—There is a theory which has scarcely yet got a name; we speak of it as the periodic law, or as the principle of MENDELÉEFF. According to this principle, stating it very broadly, all the properties of an element, physical and chemical, can be deduced by calculation from its atomic weight; that, given the atomic weight of an element, you have all that you require to find out by calculation everything connected with it. If this were so, the whole of chemistry would be derivable by calcu-

lation from the atomic weights of the elements. This is a very broad way of putting the theory, but it indicates the direction which it seems likely to take. We shall be obliged, of course, to examine it, and put it to the test. It may die of some disease of infancy or youth, or it may survive to old age. But there it is now. I may give you some illustrations of this theory without going into details. It is not many years ago that M. LÉCOQ DE BOISNAURAN obtained from the zinc ore of the Pyrenees a new metal, to which he gave the name of gallium. This metal had been expected: theory led to the belief that there should be a metal with about the atomic weight which gallium actually has. From this atomic weight the properties of the expected metal had been calculated. Now the actual properties of gallium, some of them very remarkable properties, have been wonderfully closely anticipated by the calculations. Gallium has a low fusing point, it melts with the heat of the hand; it is, however, not sensibly volatile. These physical characters and many of the chemical characters of the compounds of gallium had been predicted before any one had seen the metal, or had the least idea where it was to be found. It is curious that another discovery of the same kind should follow at no long interval. About two years ago Professor WINKLEN, of Freiburg, discovered another new metal, to which he gave the name germanium. At first there was some doubt as to its atomic weight, but when larger quantities of the substance were obtained, this was determined with accuracy, and it was at once seen that germanium was a metal that had been expected, its general properties had been foreseen. Such examples of course add to the credit of the theory, but we are still a long way from anything like a proof that all the properties of an element are deducible from its atomic weight. *Professor Crum Brown.*

"LES SERRES VERGERS."—We are glad to see that M. PYNÆRT has published a fourth edition of his treatise on forcing fruits. The new edition is considerably larger than its predecessor, and has been completely revised. We shall have further occasion of speaking of this valuable work.

"HARDY FLOWERS."—A fourth and cheaper edition of this work has been issued, and may be had at the *Garden Office*, Southampton Street. It comprises a descriptive list of upwards of 13,000 of the most ornamental species. The plants are arranged alphabetically, without any reference to their family relationships. The selections of kinds suitable for various purposes are very useful.

CHINESE PRIMULAS.—At the Winter Exhibition of the National Chrysanthemum Society, to be held at the Westminster Aquarium on January 11 and 12, Messrs. SUTTON & SOSS, of Reading, will we learn exhibit a large collection of their improved strains of Primula.

TREES AND SHRUBS.

THE SEA BUCKTHORN (HIPPOPIHÆ RHAMNOIDES).

OFTEN enough, particularly along the sea coast, do we find this pretty and distinct shrub used largely in the formation of shrubberies, but rarely do we meet with standard or single specimens planted solely for ornamental purposes on our lawns and in our grounds. This, we think, is a great pity, the truth of which was clearly enough demonstrated but a few days ago, when a couple of huge specimens—the pride and ornament of a banker's garden—were pointed out to us, and which from their long, narrow and silvery-toned leaves offered such a pretty and unusual contrast to the usually employed lawn and garden shrubs.

Of no usual dimensions were the specimens in question, one, the largest, being fully 11 feet in height and 12 feet in diameter of spread of branches, and the other but little short of these measure-

ments: indeed so regular in outline and size were these plants that they could not otherwise be described but as a well-matched pair. No long, bare stems, such as one is accustomed to see in this Buckthorn, were here presented, but simply perfect pyramids of the most perfectly developed foliage—this the result, no doubt, of the partially sheltered situation, and also of the plants being at all times given ample space for lateral spread of branch. The soil which produced these fine shrubs is a free sandy loam, largely intermixed with sea-sand, while the locality in which that grows is hardly a quarter of a mile from the shores of the Irish Sea. As an ornamental berry-bearing plant, the Sea Buckthorn is well worthy of attention, few hardy shrubs producing these in greater abundance than that in question, while at the same time they remain good for a long period, and are not so liable to the attacks of birds as those of the generality of our trees and shrubs.

By treating the fruit in a similar way to that usually recommended for the Holly, and sowing the seeds in early spring, we have been successful in raising numbers of plants, which, in two or three years, are fit for planting out permanently. [Readers should remember what nurserymen sometimes forget that the sexes are separate in this shrub so that both male and female plants should be secured if berries are wanted. Ed.]

ORNAMENTAL BERRY-BEARING PLANTS.

Now that the dull winter days are upon us, and outdoor flowers few and far between, a few words regarding the most valuable of hardy berry-bearing plants will be opportune.

The *Holly* (*Ilex aquifolium*) in its many and varied forms is, perhaps, unsurpassed for general usefulness as a berry-bearing plant, for not only is the fruit highly ornamental, but the foliage, too, and being of good substance lasts for a considerable time, even when kept out of water. In the yellow-berried variety we have a fine and distinct contrast to the normal or red-fruited plant, and when fruiting branches are placed side by side for Christmas decoration the effect produced is truly beautiful, the deep coral-red of the one and the amber hue of the other producing a very pleasing and desirable contrast. Then for variety in foliage tints we have golden and silver-blotched and margined forms, these mixing in nicely with the deep glossy green of the commonly cultivated kind.

Skimmia japonica is another excellent plant for winter decoration, the berries being produced in great abundance, and at a time when such is in most request. As a pot plant this *Skimmia* is extremely useful, it being of neat compact habit, not over large, and with highly ornamental foliage. It forces well, but in our opinion succeeds and bears fruit quite as freely when planted in peaty soil in a north-facing border.

The *Strawberry Tree* (*Arbutus Unedo*), with its curiously shaped Strawberry-like fruit, is well worthy of culture where winter decorative plants are in request. It is, however, doubly useful as an ornamental plant, for both the flowers and fruit are produced at one and the same time; and as the former are of a delightful creamy-white colour they afford a nice and pleasing contrast to the red-cheeked fruit. If placed in water both the fruit and flowers are wonderfully lasting.

To-day we could not help admiring the large pink berries of the *Butcher's Broom* (*Ruscus aculeatus*). This is rather a neglected plant, but it must be admitted by any person who has had the privilege to behold a well-berried specimen, that in point of beauty in this particular way it is no second-rate plant. The berries are large and plump, the size of a Hazel-nut, or nearly so, and of an enticing hue of red. The plant is readily cultivated—indeed, in certain localities, particularly chalky districts, it is a matter of some concern how to keep it in bounds. We have not seen it as a pot plant, but there can be no doubt, from its accommodating nature, that for this particular purpose it is excellent.

Empetrum nigrum, with its dark shining berries is, unfortunately—or, perhaps, fortunately—a summer or autumn plant, for the fruit is too delicious and tempting to both man and bird to be left alone for any length of time. We cultivated a fine patch of this plant for many years, and solely on account of its polished black berries, which were annually produced in rich profusion.

Peruetya mucronata and its many forms are highly interesting and ornamental plants, and such as can ill be spared where seasonable winter decorations are in request. Some of those sent out from a famous Irish nursery are grand, bearing fruit of almost every conceivable colour; and, what is better still, these remain on the plants and in good condition for a considerable length of time. As pot plants they are of great value, and in some instances, under successful cultivation, so freely produced were the berries that hardly a trace of foliage was to be seen. A free sandy peat, or rather sandy loamy peat, would seem to suit best this highly ornamental tribe of plants—at least under such a condition as to soil we have noted the most satisfactory results in cultivation. *A. D. Webster.*

(To be continued.)

NURSERY NOTES.

THE CHINESE PRIMULA AT SPARKHILL NURSERIES.

BIRMINGHAM has been very deservedly complimented lately on the skillfulness of gardeners of the district in producing the beautiful display of plants at the recent Chrysanthemum show, and which was freely commented on at the annual dinner of the Birmingham Chrysanthemum Society on December 14. Mr. Petch stated that it was in Primulas far away the finest display he had ever seen.

The late Mr. Tomkins, for many years the proprietor of the Sparkhill Nurseries, managed to obtain a fine strain of Primulas, from which two fine varieties, *Princess Louise* and *Marquis of Lorne*, were selected as being improvements on existing varieties, and he was also the means of giving a great impetus to the cultivation of the Chinese Primula in the neighbourhood of Birmingham.

On the death of Mr. Tomkins, the sons of Mr. T. B. Thomson, who now so successfully carry on their late father's business, secured the Sparkhill Nurseries, thus adding the nursery branch to their extensive seed business, and Primulas became especially cared for here, some of their new varieties fast gaining in popularity. At the present time an exceedingly fine batch of plants of the two varieties I have named, and others whose names will follow directly, are in the full flush of beauty, the plants of full size and abundantly bloomed, with large flowers of much substance. The *Marquis* and *Princess* were not only at the time of being introduced very distinct in the size, substance and form of the flowers, but they were distinct in the thick fleshy foliage, distinct also in form from the ordinary Primula.

This type is preserved in many of the new kinds, whilst in others the Fern-leaved section has dense and stout foliage. *Primula sinensis* The *Queen* is a Fern-leaved variety, raised here some four years since, and has a soft pink suffusion on its large white flowers, which are not quite so flat and smooth as those of the *Princess Louise*, but it is a very fine variety, and of pleasing lovely tint. Her *Majesty*, another of the Sparkhill seedlings, is a seedling from *The Queen*, also Fern-leaved, and of a more decided shade of pale rose in its pure white flowers. There are several plants of these two varieties growing in 7-inch pots—excellent examples of cultivation. There is an improved *Marquis of Lorne* not yet named which has large, bold, smooth blooms of great substance, and, like its parent, is of a shade of rosy-red. A variety named *Emperor*, of the same type, is brilliant in colour, and of a bright cerise-red. This is also one of the Sparkhill seedlings. Then there is another *Marquis of Lorne* seed-

ling named Jubilee, a Fern-leaved variety, and a good telling dark companion variety to The Queen and Princess Louise, the parent of some of the excel-

Some good double varieties have emanated from Sparkhill, the latest addition being Lady Martineau, a sport from Alba magnifica, more fringed than Peach Blossom, with larger flowers than the latter, and a very free habit, the colour a tinted pale pink.

Amongst others now in good bloom at Sparkhill were the following fine doubles, viz.:—A. F. Barron, Miss Eva Fish, Annie Hillier, Marchioness of Exeter, and King of the Purples; and these six varieties give a good variety, and would form a select collection. *D.*

VERONICA CUPRESSOIDES,
AND ITS ALLIES.

A SHORT time since there was considerable discussion in these pages concerning the nomenclature of the plant cultivated in gardens as *Veronica salicornioides*, in which no happy result seems to have

forms of the plant cultivated in gardens a *V. salicornioides*; and fig. 6 is from the plant cultivated in Hay Lodge gardens as *V. cupressoides*; from which it will be seen that no perfectly satisfactory conclusion can yet be arrived at, as none of the garden forms are exactly identical with either typical *V. cupressoides* or *V. salicornioides*. However, I think it will be clear to all that the true *V. salicornioides* (fig. 3) is distinct from the plant cultivated under this name, differing in having stouter branches, in being more strict in habit, and in having the leaves very closely set and decidedly imbricated, which is not the case in any of the forms of the plant grown as *V. salicornioides* that I have seen. So far as is known to me the true *V. salicornioides* is not in cultivation.

Now, with regard to the plant grown as *V. salicornioides*, what is it to be called? It is evidently a very variable plant, as I have endeavoured to show in figs. 5 and 5A, A to F; a and b are from two states grown in Hay Lodge garden; the same form or

FIG. 3.—VERONICA SALICORNIoidES, TYPICAL.

lent white varieties of the type of Marquis of Lorne, but with very large flowers.

I have not viewed blue Primulas with much favour, but the Messrs. Thomson have a grand thing in King of the Blues, which, so far as known blue varieties

FIG. 4.—VERONICA CUPRESSOIDES, TYPICAL.

are known about Birmingham, must be regarded as a good improvement on all the blues, possessing the foliage and vigour of Marquis of Lorne with the same size, form, and substance in the flower, which has a clear blue tint, strongly marked in the

FIG. 5.—VERONICA CUPRESSOIDES VAR. VARIABILIS, N. F. BR.

been arrived at. It therefore appeared to me that, as some of the disputants were unacquainted with the true *V. salicornioides*, a small sketch of this species would be of value as showing that the plant cultivated under this name was distinct, and having received from the Editor some specimens grown at Hay Lodge, Trinity, Edinburgh, as *V. cupressoides* and *V. salicornioides*, and some interesting forms of the latter plant grown at Kew, and the Botanic Garden, Edinburgh, kindly lent me by Mr. Dewar, I have thought it would be useful to figure small twigs of them all, as well as of the typical *V. cupressoides*, in order to make clear whatever differences may exist between them. In each case I have represented twigs that are comparable in age and condition, of their natural size, and by their side a portion of a branchlet magnified in each case five diameters. Fig. 3 is drawn from one of the type specimens of *V. salicornioides* collected by Travers on the Wairau Mountains, 4000—5500 feet elevation. Fig. 4 is drawn from one of the type specimens of *V. cupressoides* collected by Sinclair in Upper Wairau, 4000 feet elevation. Fig. 5 represents various

forms are also grown by Mr. C. Wolley Dod, Messrs. J. Veitch & Sons, and at Kew, and seem to be the more ordinary states of the plant, with small Cupressus-like leaves, only differing slightly in habit of branching, but both modes of branching may be found on the same plant; c (fig. 5A) and d are some what similar states, from Kew—in both there are some branches having only the usual small Cupressus-like leaves, and some having the leaves expanded into flat spreading blades, which are sometimes entire, as in c, and sometimes have a tendency to become lobed, as in d, which latter state I have also had from Messrs. J. Veitch & Sons. e represents a condition of the plant grown in the Edinburgh Botanic Garden, in which the majority of the leaves are very distinctly lobed, some being pinnatifid. These four states, therefore, exhibit a complete gradation from small Cupressus-like leaves to pinnatifid ones. f is from a plant grown in the Edinburgh Botanic Garden under the name of *V. lycopodioides*, but it is very different from that species, and is evidently only another modification of the plant we are treating of, and a very remarkable one it is. I have only seen a small

FIG. 5A.—VERONICA CUPRESSOIDES.

flower, and a large yellow eye. Our Primula growers are making great headway in scarlets of the Chiswick Red type, and in Thomson's Sensation we have a fine striking variety, of brilliant colour—or brilliant, resembling Sutton's Scarlet; the habit is good, and the flower well formed, and of a deep rich crimson-red colour.

twig of it; the lower leaves are somewhat distant from each other, and are pinnatifid, with acute lobes; whilst those on the terminal branchlets are very closely set, long and subulate, giving it some resemblance to a Lycopodium, whence probably the error in the name. I do not find any of the small Cupressus-like leaves on the small piece kindly lent me by Mr. Dewar, but probably they would be found on the plant if searched for. All these are, beyond a doubt, but variations of one plant, and Mr. Dewar informs me that the variations grown at Kew are all derived from one plant, and are probably due to some differences in soil and situation. But it may be asked, if this is such a variable plant, why may it not still be the same as, or a form of, *V. salicornioides*? (fig. 3). I may say that all who have compared the plant, living and dried, with the type of *V. salicornioides* agree with me in considering it to be quite distinct. Besides the differences previously pointed out, there is, to eyes accustomed to such comparisons, such a very different look about the two plants that convinces one of their distinctness.

On looking to the figure of typical *V. cupressoides* (fig. 4), it will be noted on comparing the magnified portion with that of fig. 5A, that the leaves

var. *variabilis* is a distinct species or merely a variety, as with our present knowledge it appears to me most judicious to consider it. The flowers of this plant are white, whilst those of typical *V. cupressoides* are stated to be violet; but unless there are some other differences in the flowers, of which I have no opportunity of judging, no importance can be attached to this, I think, as most of us are familiar with the fact that the flowers of the same species of *Veronica* vary considerably in colour. *N. E. Brown.*

FOREIGN CORRESPONDENCE.

THE ROSES OF THE SOUTH.

We extract the following article from a French contemporary, thinking it may be of interest to our readers:—

"The Parisian adores flowers. He could not live without them, and, when the squares are despoiled by the frost, offering nothing to the sight but sad ruins, he demands from Provence those resplendent flowers which bear with them a little of the bright sun of the South. How many of the per-

light straw matting, which are removed in the morning at 9 o'clock. This work entails a large amount of labour, and we think that everywhere where an extended cultivation permits of it, the growers of Roses could advantageously make use of artificial clouds, made by the fumes of thick oil, and which, in the east, have succeeded perfectly in keeping the young Vine-shoots from May frosts. Among the most esteemed varieties of Roses we may mention the following:—*Maréchal Niel*, of a yellow colour; *Malmaison*, tinted with clear rose; *Gloire de Dijon*, fawn, mingled with red; *Papa Gontier*, clear red; *Général Lamarque*, pure white; *Marie Van Houtte*, yellow, with a reddish tinge; *Duchess of Edinburgh* red; and *Isabella Nabonnaud*. The least delicate and therefore the most common, is the *Safrano*, the tint of which, as its name indicates, approaches that of saffron. The *Safrano* sells wholesale at Cannes at from 3*l.* to 10*l.* per dozen; the *Maréchal Niels* fetch four or five times more. Roses have been for a long time cultivated at Nice and Cannes, but previously to 1867 they were only utilised for the purpose of making perfumery; it was the restricted outlet which limited the production. From the arrival of Alphonse Karr on the Mediterranean littoral dates the flower industry for bouquets or cut flowers.

"The author of *Guépes* set up a floral establishment at Nice, and his villa of Saint Raphael became a celebrated nest of Roses. These examples were not thrown away, and Hyères, seeing its Vines perish,

FIG. 7.—VERONICA CUPRESSOIDES VAR. VARIABILIS. (REAL SIZE.)

FIG. 8.—VERONICA CUPRESSOIDES, HAY LODGE GARDEN.

are very similar in both, and if those of fig. 1 were placed closer together there would be very little difference between the two and some specimens in the Kew Herbarium which have been considered to be true *V. cupressoides* look very like the *V. salicornioides* of gardens, but there are no specimens in the Herbarium which show any tendency to variation like that of the garden plant, so as this is of decidedly dwarf habit than the typical *V. cupressoides*, and whether the same species or not, is sufficiently different to require a distinctive name; and taking its variable character into consideration I propose to call the *V. salicornioides* of gardens *V. cupressoides* var. *variabilis* (fig. 7).

The *V. cupressoides* of gardens (fig. 6) is quite like the typical form in habit, but, as will be seen from the figures, the leaves are not quite the same; but as they are seen to be so variable in the dwarf plant, this slight difference may, I think, be neglected, and the plant be considered to be true *V. cupressoides*; especially if we call to mind how the leaves of many other plants of New Zealand and other countries vary—such, for instance, as obtains in the species of *Dacrydium*, &c. It would be interesting to know from what part of New Zealand the garden plants came, as this might help to solve the present doubt as to whether the dwarf plant which I have called *V. cupressoides*

sons who stop before our florists to admire in December Roses superb in their freshness, ask one another, 'How is it possible to obtain such flowers?' And many doubtless believe there is some astonishing and mysterious cultural process. There is nothing of that. The great—one might almost say unique—producer of Roses is the sun; but not this poor winter sun, so sparing of its rays. It is the sun of the Midi, bright and warm, and which a sojourn is delicious at Cannes, Nice, and the whole of the littoral, from Hyères to Mentone. It is to this mild temperature, which, thanks to the mountains, the north wind rarely comes to modify, and also, doubtless, to the saline breezes, that the Rose bushes possess an exceptional vigour. To speak truly, there are no fields of Rose bushes; the Roses are cultivated in the hedges, around the villas, and in the gardens picturesquely arranged in terraces. Certain delicate varieties, or those loving to climb, are trained *en espalier* the length of the walls. This is an excellent course. In this climate Roses have but two enemies—wind and white frost. The wind, shaking the Roses, bruises them, so that they last a less time and must be sold in the environs at a very low price. White frosts are rare, but where they do appear they stop the development of the Rosebuds and seriously affect the number of blown Roses. Thus careful owners in the evening cover their Rose bushes with cloths or

also devoted itself to flower culture. The annual exportation of Roses from the South of France is estimated at a sum of £200,000 sterling."

MARKET GARDENING IN FLORIDA.

I have read with great interest the article on Market Gardening, by Mr. Wm. Earley, of Ilford, in the *Gardener's Chronicle*, page 75, July 18, 1885, vol. xxiv., No. 603, a copy of which I have just received from a friend in England. I am inclined to agree with the writer on all the points named in his article, and particularly in regard to close planting of Cabbages. I am growing an acre of Cabbages (Burpee's Short-stem Drumhead and Burpee's Sure-head), many of which are now ready to cut, and all the rest heading nicely. These were sown in August last, and are planted (being so advised by old resident farmers) 2 feet apart in the rows and the rows 4 feet apart from each other. Between each four rows of Cabbages is a row of young Orange trees, each plant 20 feet apart each way. Had I seen the article of Mr. Earley sooner, I should have tried the system he advocates of close planting. I regret he did not name some of the varieties of Cabbages suitable for close planting, as I feel sure "good medium-sized, well-hearted heads are preferred" in America as well as in England.

Will your correspondent, therefore, kindly furnish the information required in some future issue of your excellent paper? I arrived in Florida last

April, and am delighted with my experience of the Land of Flowers so far, and am contemplating sending you a short article on Florida, its climate and fruits if agreeable to your readers. *Box 147, Waldo, Alachua Co., Florida, U.S.A.* [Please to carry out your intention. Eo.]

CULTURAL MEMORANDA.

PERPETUAL FLOWERING CARNATIONS.

THESE favourite flowers should have free circulation of fresh air during fine mild weather, and when the temperature of the house is not below 55°, otherwise the plants will make a weakly growth. The flower-stems should have support. As the flowers open a piece of matting should be tied loosely round the calyx, to prevent its bursting. Andalusia, primrose-yellow, fringed petals; Miss Jolliffe, pale pink; La Florifère, pure white; Empress of Germany, large white, slightly marked rose; Worthington Smith, deep scarlet; and Valencia, dark crimson Clove-scented, are a few of the best varieties to grow, the plants being vigorous growers. Care must be exercised in giving water. When the soil becomes a little dry on the top, give sufficient water to moisten the ball thoroughly. Alternate waterings of weak liquid manure and clear water at a temperature of about 70° will assist in the development of large flowers. Should aphid attack the plants, fumigate lightly with tobacco-paper two evenings in succession. *H. W. W.*

PANCRATIUMS, &c.

Mr. Thorpe, speaking at Chicago, recommended that those, as well as Crinum and Amaryllis plants, should have all the encouragement possible till the leaves are thoroughly developed. As soon as this takes place the water should be stinted and the plants allowed to go to rest. Pancratiums require a temperature of not less than 55° at any time. Whilst they are at rest, a top shelf, where they can get the benefit of the light without the direct rays of the sun, is the best position for them. As soon as they show signs of growth they should be watered, gradually increasing the supply as the leaves grow.

ROSE CELINE FORESTIER.

From plants of this free-flowering Noisette Rose we have been, during the last few weeks, cutting half-opened pale yellow and very fragrant blooms, which, set up on its own pale green foliage, came in very useful for buttonholes, as well as for filling small vases and glasses in the boudoir and drawing-rooms. Cuttings taken off any time this month with a little of the old wood attached, and inserted in properly drained 3-inch pots filled with light sandy soil, watered and placed in a hotbed or on a shelf in the stove, or anywhere in heat, will soon take root. They should then be potted off singly into small pots, using a compost of three parts sandy loam and one of sweet leaf-mould, putting the plants back in heat near the glass, and afterwards attending to them in the way of watering, and in due time shifting them into larger pots as the plants require more room at the roots, and gradually hardening them off before plunging the pots to the rims out-of-doors in coal-ashes in a sunny situation early in the summer, giving weak liquid manure at the roots about three times a week during the summer and early autumn months. Thus treated they will make nice useful plants for supplying blooms next Christmas. *H. W. W.*

ASPARAGUS PLUMOSUS.

The pale green flat Fern-like fronds of this South African Asparagus are far superior to the popular Maidenhair Fern (*Adiantum cuneatum*) for button-hole and bouquet work, inasmuch as the fronds keep fresh much longer in a cut state than those of *Adiantum cuneatum* do. Plants in pots ranging from 3 to 6 inches in diameter are also very useful for decorative purposes; but where there is much

table decoration and buttonhole work to do a few plants should be grown on in 9-inch pots for cutting from. This Asparagus, like its allies plumosus nanus, tenuissimus, and virgatus, is easily increased by division of the roots, potted in a mixture of equal parts of light sandy loam and peat, with a sprinkling of small charcoal and sharp sand added, afterwards putting the plants in a stove or Cucumber-house, or in any structure in which a growing atmospheric temperature is maintained, giving water at the roots when the condition of the soil renders its application necessary. *H. W. W.*

THE COLEUS.

About twenty-five or thirty years ago the Coleus was represented in catalogues generally by two varieties—Blumei and Verschaffeltii. Now there are to be found as many as 130 named varieties in some of the leading plant catalogues. The leaves of many of these are undulated, deeply serrated, veined with rose, white and red, and beautifully spotted and margined. Therefore, judiciously pinched plants from three to fifteen months old are very useful for furnishing rooms, &c. The tops of shoots having two or three joints each, taken off now and inserted singly in 3-inch pots filled with light mould placed in heat and watered, will become rooted in a few days, and quickly attain to useful dimensions. *H. W. Ward.*

THE FLOWER GARDEN.

PENANS no apology is needed at the present time for a brief retrospect of the past year, which, in so far as regards the flower garden and pleasure grounds, may be said to have been one of a somewhat eventful character, and fruitful of incidents, which, if taken separately or collectively, afford matter for thought and reflection, and which should furnish us with something in the nature of a guide in the future, and convey useful lessons in practice. From the gardening point of view the chief characteristics of the year were, an unusually long and severe winter, which in many instances was productive of disastrous results amongst trees and shrubs. The ground being for a long period frost-bound, planting operations were necessarily postponed to a later period than is generally considered advisable, and, as a necessary consequence, much extra work was entailed in the way of mulchings and watering during the warm weather. Especially was this the case in hilly districts, and on gravelly soil; and in such situations, unless these precautions were taken, an unusual number of failures resulted, particularly amongst large specimens of trees and shrubs. With such severe weather as was experienced in March, when on several occasions the temperature fell to very low readings, it is not surprising that herbaceous plants in beds and borders suffered serious loss, of course this being greatest where much had been left to chance or the protection was insufficient. The lessons taught us will be lasting. Notwithstanding the spring was backward, and was followed by a summer almost tropical in its heat, which entailed a large amount of watering amongst newly planted stuff, the harm caused was more than counterbalanced by the good results derived from the fierce summer. With the wood of all trees and shrubs well ripened, and bulbs, roots of hardy plants well matured, and where the requirements of the plants were duly attended to, we may hope to witness a wealth of bloom in due season.

Planting, Pruning, and Protection.—When the state of the weather will permit, push forward any alterations needed, and with the planting of trees, shrubs and Conifers of most kinds of a hardy nature, but do not remove Hollies or Sweet Bays. As the work proceeds stake and tie all such as require it, and finish off with a good mulching of half-decayed stable manure, or, in the absence of this, litter and leaves; the latter, however, are rather objectionable in well-kept grounds, unless kept in place by a sprinkling of soil, as in rough windy weather they invariably get blown about in all directions. Do not prune any shrub or tree, if it can be avoided, during frosty weather, but rather defer the necessary pruning of deciduous trees and shrubs until later. Overcrowded shrubby borders and clumps should receive attention in the way of thinning out and cutting down where it is required, grubbing out old stumps, turn-

ing in all fallen leaves without disturbing the roots, so as to give the ground a neat and clean appearance. Cut and trim hedges of Quick Beech Privet, and others of a similar nature, cleaning out all weeds and rubbish from the base. Afford protection to all such subjects as require it, and where previous experience has proved it to be unwise to go without. In herbaceous beds and borders many perennials will be benefited by a covering of cinder ashes or cocoanut fibre refuse, amongst them being the more tender species of Liliium, Lobelia fulgens, L. syphilitica and their varieties, Dielytra spectabilis, Iris reticulata, and others of a kindred nature. Helleborus niger and its varieties will well repay by being covered with hand-lights and freely ventilated on all favourable occasions.

Flower-beds.—Manure and dig over unoccupied flower-beds, leaving the surface rough so as to get well pulverised. Others containing Hyacinths and early flowering Tulips should be protected from severe frosts by a good covering of cocoa refuse. Keep a vigilant outlook for mice amongst the bulbs of Crocus. Beds filled with such spring flowering plants as Arabis, Myosotis, Polyanthus, Violas, and double-flowered Daisies will require attention after a spell of sharp weather, and should be pressed down quite firmly with the hands. *J. Horsefield, Heytesbury, Wilts.*

HOME CORRESPONDENCE.

Correspondents will greatly oblige by sending early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Photographs or drawings of gardens, or of remarkable plants, trees, &c., are also solicited.

EICHORNEA AZUREA, MART.—Mr. Morris suggests among other theories that the swollen petioles of this plant may act as sails to waft the plants to the edges of ponds, and possibly also to the nutrient mud. In Pernambuco, where I saw it growing wild, the plant only grew in streams, jutting out from the bank very much as *Heteranthera reniformis* does. Is it not more likely that the floats are destined to enable a broken-off plant to be carried down the stream, and so diffused? *E. speciosa* is very common round Pernambuco. You may see the low, swampy fields pink with its beautiful flower-spikes for a long distance. This plant, which has better developed floating petioles than *E. azurea*, does not grow under shade, but in open fields, either simply in the wet mud or in shallow water; in fact, its habits are very much those of the Watercress. I do not doubt that the floats in this case are to diffuse the plant when a bit is broken off by a flood. As the rhizome is attached to the ground, of course the plant cannot be raised up by a flood more than an inch or two without the rhizome being broken. *E. tricolor*, is almost the commonest of the three species round Pernambuco. I have not seen it in cultivation. It is, to my thinking, the most beautiful of all the species. The inflorescence is a panicle with spreading branches, often 6 inches long, covered with the blue, yellow, and violet flowers. The figure in the *Flora of Brazil*, vol. iii., t. ii., represents a small and young specimen, and gives no idea of what the plant can become. It grows in ditches and water-courses running through swampy fields, and often quite chokes them up. *H. N. Ridley.*

NEW VARIETIES OF POTATOS.—Your correspondent "X." will greatly oblige if he will be kind enough to give me the names, through the medium of your columns, of two or three varieties of new Potatos suitable for field cultivation. It is necessary that that purpose they should be of robust constitution, the tubers of fair size and shape (kidney-shaped or flat round), and when boiled they should be of good colour, either white or yellow, and that the insides will cook through before the outside are "pasty"—a common fault with many kinds—*i.e.*, they are not firm enough in texture to admit of their being properly boiled through to the centre before the outside are all "pap." A Potato suitable for exhibition and one suitable for family use is a Potato of another kind. I have from time to time proved many so-called new kinds and have found them wanting. The American varieties, from "Roses" downwards, have all proved deficient in flavour on my soil. The best flavoured Potato that I ever

grew (previous to the Potato disease) was a variety called the Old Winter Dutch (I believe they came from abroad), the last of which I sent to the late Wm. Tillery, at Welbeck, several years since, he having made enquiry for them through your columns. Since the appearance of the Potato disease I have grown York Regent, Flukes, Balhadereen, an Irish kind, Champions, Paterson's Victoria—the best of any Magnum Bonum, and lastly, Reading Hero. These have all done duty in their turn, and the last-named must give way for something fresh to the soil. I may add that I know of only two kinds of Potatoes that were grown previous to the spread of the Potato disease that I can now find anywhere in this locality, viz., Ashleaf and Early Shaws; the last-named had a flavour peculiar to itself, which none of the recent introductions that I have grown possess, excepting, perhaps, the old Lapstone Kidney. The great fault with so many kinds of Potatoes is want of constitution, *i.e.*, they have no woody fibre in their stems, and their tubers are soft and tasteless (otherwise they are sweet, earthy, or disagreeable) instead, of that quality of texture which is firm, but yet yielding to the pressure of the fork when cooked, and of a somewhat nutty flavour, which is rather difficult to describe on paper. *North Norfolk.*

BEDDING OUT.—In "G. B.'s" article of December 17 on "Bedding Out," I was pleased to see a change advocated, as regards the massing of showy flowering plants, in the centre of a lawn, but would like him to go a little further and say what he would do with "the border" the remaining eight months of the year. *W. B. Jeffreys, Blackheath Park.*

THE ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—Permit me to suggest that the formal meetings of the Fellows of the Royal Horticultural Society to be held on the 10th should be taken advantage of by the Council to make some statement as to the future constitution of the Society's professional committees, and the nature of the qualifications of members. I ask that, because in the first place I learn that it is proposed to appoint none to the committees except they be Fellows—a course which I would not question if the Council would bring down their rate of annual subscription, so as to suit the pockets of gardeners generally. If the present high rate be continued it is but too evident that many of the most useful elements of these committees must be excluded from them. But whilst the present arrangement exists of admitting other than Fellows to the committees, it would certainly tend to the giving of some much needed confidence in the Society if the President would make a clear and authoritative statement as to how appointments are made, who selects the favoured individuals, why so selected, and on what grounds certain others are removed annually. The Council must know—indeed, it is perpetually referring to the work of its committees as evidence of the Society's usefulness—that these committees are called upon to discharge duties of the highest horticultural interest and confidence; and the manner in which those duties are discharged can only be appreciated by letting the fullest daylight in upon the method now adopted of selecting the committee members. *Spade.*

BRUGMANSIAS.—I have in a cool conservatory at this place a large plant of *Brugmansia suaveolens*, and one of *B. sanguinea*. I think formerly [and now] they were called *Datura*. I cannot find *Brugmansia* in Loudon, or any other Botanical book I possess. *B. suaveolens* has produced since last May 139 flowers, and *B. sanguinea* 94. Last month a great number of flower-buds fell off both plants, and at the present time *B. sanguinea* has flowers which are nearly opened. The conservatory is not maintained as a warm one in the winter, but in the summer-time the sun shines in very warm in the morning, but after mid-day the house gets shaded by a large Cedar of Lebanon. The plants are afforded plenty of water as they stand near to the hot-water pipes. I should be much obliged by any information respecting the proper soil and treatment. *M. Freeman, Ryton-on-Dansnore, Coventry.* [See our Answers to Correspondents. Ed.]

FERTILISING MOSS.—We feel much indebted to Mr. Roberts for his letter on this subject. As plants, both soft and hard-wood, are benefited by being potted in the moss, Mr. Roberts instancing *Bouvardias* and *Gloxinias*, quite justifies its use. I had mentioned *Fuchsias* and *Gloxinias* as being plants benefited by its use. It is a perfectly true statement about the *Bouvardias* in 6-inch pots

bearing thirty to forty heads of bloom each. I remarked in Mr. Roberts' note the statement that plants which endure for many years do well when the moss is used as a top-dressing which I can easily understand, and if the moss is superior to peat and loam in porosity and in capability of absorption, it would be appropriate for some species of *Orchids*, and is what I intend to experiment on shortly. Mr. Roberts does not underrate the good qualities of loam; he also gives clear reasons for in some instances preferring moss. It is now time some capable cultivator should give us some principles to guide us in the use of this new substitute for mould, there being nothing so useful as the power to combine theory and practice. *W. Bell, Annesley Park.*

POPULUS PYRAMIDALIS MEETENSIS.—I am interested in the note concerning this tree at p. 818, Dec. 31, but am puzzled somewhat about M. Mathieu's description of it. If, as he says, the Metz Poplar is like the Fulham Oak (*Quercus fulhamensis*) in growth, then it cannot be columnar in the sense that the term is generally understood. If it be really a pyramidal or columnar outline, and so rapid and vigorous in growth, it will surely be worth the attention of English nurserymen. Though not a lover of the Canadian Poplar, or any other Poplar of similar habit, I should be glad to see one that, while not so strictly columnar as the Lombardy, has not the monotonous rounded outline of the too familiar Black Italian. [Try Bolle's poplar. Ed.] Again, as to the name of the Metz Poplar, will it not lead to confusion if it is named *P. pyramidalis*, seeing that the Lombardy is also known by that name? *P. Eugène* is a more distinct name, but according to the new order of things I suppose it ought to be *P. canadensis Eugène Simon!*—seeing that it is but a seminal form of *P. canadensis*. I should be glad of further information about this Poplar, as, so far as I can ascertain, it is not in English nurseries, though large trees of *P. Eugène* are said to exist in England. I should like to know also the origin of the Poplars known in English nurseries as the Giant Lombardy and *P. canadensis nova*. Perhaps one of these is identical with MM. Simon-Louis' seedling. *W. Goldring, Kew.*

GOOSEBERRIES.—Some time since one of my market garden neighbours sent off into Kent a load of 12,000 Gooseberry bushes for planting, and all of two kinds only—Lancashire Lad and Crown Bob. It is interesting thus to learn that in spite of outbreaks as to fruit depreciation, there are still growers who have faith in the future. This consignment is but one of many from this district, and but a comparatively infinitesimal one for the whole kingdom—pretty conclusive evidence that we shall not give up the growing of market Gooseberries just yet. This one lot of 12,000 of two-year-old bushes should plant some 6 to 8 acres of ground, but of course all depends upon the fashion of planting. A few years hence and the breadth will add a thousand bushels of fruit to the general produce. Still it is obvious that such breadths of young Gooseberries are not all gain. Every year old exhausted breadths are being grubbed out, and younger ones are replacing them. It is hard to say how long Gooseberry bushes will endure, but one of the finest breadths in this country just now is nearly twenty years old, and with hard thinnings would pay to stand ten years longer. All depends upon the nature of the top crop—for bush fruits are usually so handicapped—and its density. If the standard trees be not too thick, and be kept well pruned, the Gooseberries are similarly treated, the soil beneath kept clean, frequently forked, and regularly manured, it is difficult to place a limit upon the cropping duration of Gooseberry bushes. In too many gardens breadths are choked with weeds and killed by neglect; once the roots are full of Couch-grass and Convolvulus, and absolute cleaning becomes impossible, whilst a year or two's neglect leaves no other course open but to grub bushes and weeds out clean, and manure the soil and start afresh. That sort of thing is common enough amongst market garden failures: indeed, the men who go to the wall are invariably the lazy and the neglectful, whilst the best attention to all matters as invariably produces the best results. Market growers who have considerable areas of bushes find it to their interest to do these well, even for the production of good robust wood, for the formation of cuttings, because if even some 20,000 to 30,000, or even more, be annually propagated, a market is pretty sure to be found somewhere. It is

a fortunate thing for the work-people, men and women, when Gooseberry and Currant bushes are thus propagated. The pruning is got through early; women gather up and trim the cuttings, counting them and tying into bundles, whilst the men find welcome employment in planting them. Given a good season, and 90 per cent will root, and if the soil be good and the weather favourable, quite 50 per cent will make nice bushes for planting the first year, and oftentimes many are so sold. If the spring be harsh and dry, breaking is checked, and rooting is slow and late, so that but little top-growth is made that season. In the following winter these yearlings are, as a rule, lifted, trimmed hard top and bottom, and then, some ground being well manured and deeply ploughed, the young bushes are dibbled out in rows, sometimes with the aid of a line, after the ground has been harrowed, and sometimes in the furrow lines left by the plough. The course of treatment is rough, but seems to be very efficacious, especially in the production of nice clusters of fibrous roots which mark the bushes when they are lifted in the following autumn for sending away. Of the two sorts of Gooseberries named, Lancashire Lad is by far the most popular. It is just a little later in breaking than is the Crown Bob, and of course a little later in fruiting; but the Lad is rather the hardier of the two, and seems, because a little the latest in breaking, less subject to the attacks of birds—a matter of great importance in all cases, but specially so in market orchards in which there are many thousands of bushes grown. Both the sorts referred to produce fine fruits, which swell up early and soon fill the bushel. Remarkably useful in the giving of employment are Gooseberries, and in many ways good crops add exceedingly to the national wealth. Without doubt bushes have their very prolific lives lengthened appreciably by the fact that the demand for early green Gooseberries helps to denude them of their heavy crops before these have begun to prove exhaustive, and the bushes thus get rest, and at the same time ample opportunity ere the leaves fall, to recuperate and plump buds for another year. On the whole there are few fruits more serviceable in many ways than are Gooseberries. *A. D.*

SOCIETIES.

ROYAL HORTICULTURAL.

The following list, which has been sent to us for publication, contains the name of those gentlemen who have been chosen to sit on the various committees during the year 1888:—

SCIENTIFIC COMMITTEE.

Chairman.—Sir Joseph Dalton Hooker, K.C.S.I., M.D., C.B., F.R.S., V.P.L.S., The Camp, Sunningdale.

Vice-Chairmen.—Maxwell T. Masters, M.D., F.R.S., Mount Avenue, Ealing, W.; Rev. M. J. Berkeley, F.R.S., Sibbertoft, Market Harborough; F. P. Pascoe, F.L.S., 1, Burlington Road, Westbourne Park, W.

Hon. Secretary.—Rev. Professor G. Henslow, M.A., F.L.S., F.G.S., Drayton House, Ealing.

Bennett, Alfred W., M.A., B.Sc., F.L.S., 6, Park Village East, W.

Boscawen, Hon. and Rev. J. T., Lamorran, Probosc, Cornwall.

Boulger, G. S., 9, Norfolk Terrace, Bayswater, W. Burbridge, F. W., F.L.S., Trinity College Gardens, Dublin.

Church, A. H., F.C.S., Royston House, Kew.

Clarke, Colonel R. Trevor, Welton Place, Daventry.

Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire. Glaisher, James, F.R.S., Dartmouth Place, Blackheath, S.E.

Green, Professor, Pharmaceutical Society, 17, Bloomsbury Square, W.C.

Low, Dr. Wm. Hy., Woodcote, Inner Park Road, Wimbledon.

Llewellyn, J. T. D., F.L.S., Penllergare, Swansea.

Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.

Maw, Geo., F.R.S., Benthall, Kenley, Surrey.

McLachlan, R., F.R.S., Westview, Clarendon Road, Lewisham, S.E.

Michael, Albert D., F.L.S., Cadogan Mansions, Sloane Square, S.W.

Morris, D., F.L.S., Assistant Director, Royal Gardens, Kew.

Murray, G., F.L.S., Natural History Museum, South Kensington, S.W.
 O'Brien, James, West Street, Harrow-on-the-Hill, Ploveridge, C., F.L.S., 7, King Street, King's Lynn.
 Ridley, Henry N., B.A., F.L.S., Natural History Museum, South Kensington.
 Scott, D. H., M.A., Ph.D., S, Thornton Hill, Wimbledon, S.W.
 Smece, A. H., The Grange, Wallington, Surrey.
 Smith, Worthington G., F.L.S., High Street, Dunstable.
 Tait, Alfred W., 115, Entre Quintas, Oporto.
 Ward, Professor Marshall, The Laurels, Englefield Green, Staines.
 Wilson, Geo. F., F.R.S., Heatherbank, Weybridge Heath.

FLORAL COMMITTEE.

Chairman.—G. F. Wilson, F.R.S., Heatherbank, Weybridge Heath.
Vice-Chairman.—Rev. W. Wilks, Shirley Vicarage, Croydon; Major Ledy, F.G.S., F.L.S., Sunbury-on-Thames; H. Herbst, Kew Road, Richmond, Surrey.
Secretary.—Archibald F. Barron, Royal Horticultural Society, Chiswick.
 Baines, Thomas, Fern Cottage, Palmer's Green, N.
 Ballantine, H., The Gardens, The Dell, Egham.
 Bates, W., Poulett Lodge Gardens, Twickenham.
 Bennett, H., Shepperton, Walton-on-Thames.
 Cant, B. R., Colchester.
 Dean, R., Ranelagh Road, Ealing, W.
 Drury, C. T., 10, Philpot Lane, E.C.
 Domy, John, H., Tadema Road, Chelsea, S.W.
 Duffield, G., The Gardens, Bramford Lodge, Winchmore Hill, N.
 Fraser, John, Lea Bridge Road, Leytonstone, E.
 Goldring, Wm. 52, Gloucester Road, Kew.
 Hibberd, J., Shirley, 1, Priory Road, The Green, Kew.
 Hill, E., The Gardens, Tring Park, Tring.
 Holmes, W., Frampton Park Nurseries, Hackney, E.
 Laing, John, The Nurseries, Forest Hill, S.E.
 Lowe, Dr. W. H., Woodcote, Inner Park, Road, Wimbledon.
 Masters, Maxwell, T. M.D., F.R.S., Mount Avenue, Ealing, W.
 Nicholson, G., Royal Gardens, Kew.
 Noble, C., Summingdale Nursery, Bagshot.
 O'Brien, James, West Street, Harrow-on-the-Hill.
 Paul, George, The Old Nursery, Cheshunt, Herts.
 Pilcher, Charles, 84, Ringford Road, West Hill, Wandsworth, S.W.
 Pollett, H. M., Fernside, Bickley, Kent.

 Willard, Jesse, The Gardens, Holly Lodge, Highgate, N.
 Woodbridge, John, The Gardens, Syon House, Brentford.
 Wright, John, 171, Fleet Street, E.C.

SCOTTISH HORTICULTURAL ASSOCIATION.

At the ordinary monthly meeting of this body on the 3rd inst., Mr. D. P. Laird, President, a paper entitled "A Chat About Hollies," by Mr. G. Nicholson, Kew, was read by Mr. Robertson Munro.

Another paper, entitled "Horticultural Notes," was read by Mr. Milne, and Mr. Todd gave some interesting particulars respecting the experiences of those engaged in the florist's trade.

Mr. James Grieve, Local Secretary of the Scottish Primula and Auricula Society, directed the attention of the meeting to a rumour that the Royal Caledonian Horticultural Society had been communicated with by Mr. Gair, of Falkirk, respecting an offer by Mr. Lightbody, a son of the late Mr. Lightbody, the eminent Auricula grower of that town, of £150 in trust, the interest of which was to be devoted annually to a prize for the encouragement of Auricula culture, and to be called "The Lightbody Memorial Prize."

The rumour was confirmed by Messrs. D. P. Laird and Milne, both of whom are members of the Council of the Royal Caledonian Horticultural Society, who also stated that arrangements were not yet completed with regard to the proposed trust between the donor and the Society, but that more would be known of it after next council meeting.

Obituary.

PROFESSOR DICKSON.—The death, on December 30, under sad circumstances, of Dr. Alex. Dickson, Professor of Botany in Edinburgh University, is announced. Professor Dickson had been spending the Christmas vacation at his Peeblesshire home of Hartree, and while on the ice there he died. He was very fond of curling, and it is supposed that he was engaged in his favourite pastime when he was suddenly seized with illness. Professor Dickson was born in Edinburgh in 1836, and graduated in medicine at Edinburgh University in 1860. From an early age he devoted much attention to botanical inquiries, and his interest in scientific subjects increased with years. In 1862 he conducted the class of botany in the University of Aberdeen during the illness of Professor Dickie. Four years later, he was appointed to the Chair of Botany in the University of Dublin, on the death of Dr. W. H. Harvey; and in 1868 he became also Professor of Botany in the Royal College of Science, Dublin. In the same year he was appointed Professor of Botany in the University of Glasgow, in succession to Dr. Walker-Arnett, and he filled that office until 1879, when he was translated to Edinburgh as Professor of Botany in the University of Edinburgh, and Regius Keeper of the Royal Botanic Garden. His researches in some of the most difficult departments of Botany are very important contributions to botanical science. A new class-room was built at the Edinburgh Botanic Gardens shortly after Professor Dickson was appointed to his office, and he afterwards arranged for the old class-room being converted into a laboratory for microscopic experiments. The changes which have been made at the Botanic Gardens—mainly in the interests of students—have effected a considerable improvement on the former state of matters, and they may be said to be almost altogether associated with the time of Professor Dickson. His life was a quiet and unostentatious one, and he had endeared himself to his students, who found in him the most approachable of teachers. He had also gained the affections of those with whom he was associated as a country gentleman. Professor Dickson was an honorary M.D. of Dublin, LL.D. of

Glasgow, F.R.S. Edinburgh, Fellow of the Linnean Society, and twice President of the Botanical Society of Edinburgh. He was also a Deputy Lieutenant for the county of Peebles. The appointment to the vacant Chair is in the hands of the curators of the University. *Scotsman*, Dec. 31, 1887.

FRUIT REGISTER.

KEEPING OF APPLES, &c.

We find here that Apples are keeping better this year than during the last three seasons, and certainly it is several years since such a sound and good crop was harvested; but be the crop ever so good, their good keeping depends on the time when they are gathered, manner of storing, &c. We find the flavour of the fruit is much better than usual, this being remarkable in Beurré Rance Pear. I may safely say this variety has not been fit to eat hereabouts since 1878. The best late Pear found in the fruit-room at Bughley was Passe Colmar, a variety that has the valuable property of ripening its fruits over a longer period than most other Pears, and which is always good in this district. The same cannot be said always of Bergamot d'Espere, Easter Beurré, Ne Plus Meuris, and Beurré Sterckmans, which are, however, of very fair quality this season.

I noticed at Bughley a fine sample of Wellington Apple, also of Barnack Beauty, a local variety which will probably be very largely grown in a few years' time, when better known, as few can surpass it for cropping and keeping qualities. *W. H. Divers, Ketton Hall.*

THE WEATHER.

THE PAST WEEK.

The following summary record of the weather for the week ending Jan. 2, is furnished from the Meteorological Office:—

"The weather has been cloudy or dull generally with occasional falls of cold rain, sleet, or snow. The snowfall which was experienced at the commencement of the period on the south-eastern coasts of England was very heavy.

"The temperature has continued below the mean in all districts, the deficit ranging from 4° in Scotland, to 5° or 6° in Ireland, and to as much as 6° to 8° over the greater part of England. The highest of the maxima, which were recorded on December 27 in Scotland, and on January 2 in England and Ireland, ranged from 42° in 'Scotland, N.,' and 'England, N.E.,' to 49° in 'Ireland, S.' The lowest of the minima, which were recorded on irregular dates, ranged from 13° in 'Scotland, E.,' and 'England, N.W.,' and 15° in 'England, E.,' and 'England, S.W.,' to 23° in 'Scotland, N.,' and 'England, N.E.,' and to 27° in the 'Channel Islands.' At the end of the period the thermometer was rising decidedly in all parts of the kingdom.

"The rainfall has been less than the mean in all districts.

"Bright sunshine has been very little prevalent, the percentage of the possible amounts of duration ranging from 5 to 13 in most districts. In 'England, E.,' however, 25, and in the 'Channel Islands' 39 per cent. was recorded."

MEAN TEMPERATURE OBSERVED AT CHISWICK DURING THE WEEK ENDING JAN. 14. (AVERAGE OF FORTY-FOUR YEARS.)

POST OFFICE REGULATIONS.

INLAND Letters, not exceeding 1 oz., 1*½* d.; exceeding 1 oz. and not exceeding 2 oz., 1*½* d.; exceeding 2 oz. and not exceeding 4 oz., 2*½* d.; and so on, 3*½* d. being charged for every additional 2 oz.
 BOOK-PACKETS (not more than 5 lb. in weight, 18 inches in length, 9 inches in width, and 6 inches in depth), may be sent to any part of the United Kingdom. The postage is 3*½* d. for every 2 oz., or fraction of that weight. There must be no letter, or any communication of the nature of a letter, written on any part of a book packet.

INLAND MONEY ORDERS.

The commission on Inland Money Orders is:—For sums not exceeding £1, 2*½* d.; sums above £1 and not exceeding £2, 3*½* d.; sums above £2 and not exceeding £4, 4*½* d.; sums above £4 and not exceeding £7, 5*½* d.; above £7 and not exceeding £10, 6*½* d.

POSTAL ORDERS.

Postal Orders for certain fixed sums, from 1s. to £1, are now issued to the public at all Post Offices at which Money Order business is transacted, and at Malta, Gibraltar, and Constantinople.

The following are the amounts for which Postal Orders are issued, together with the postage payable in respect of each Order:—1s., 1*½* d.; 1s. 6*½* d., 3*½* d.; 2s., 1*½* d.; 2s. 6*½* d., 1*½* d.; 3s., 1*½* d.; 4s., 1*½* d.; 4s. 6*½* d., 1*½* d.; 5s., 1*½* d.; 7s., 6*½* d.; 10s., 6*½* d.; 1*½* l., 15s., 1*½* l.; 2*½* l., 1*½* l.

POST CARDS.

Post Cards, which bear a half-penny impressed stamp, are available for transmission between places in the United Kingdom. They may also be posted to foreign countries by fixing adhesive stamps to cover the extra cost for postage.

STOUT CARDS.		THIN CARDS.

2 ... 2 <i>½</i> d.	5 ... 6 <i>½</i> d.	2 ... 2 <i>½</i> d.	5 ... 6 <i>½</i> d.
3 ... 4 <i>½</i> d.	6 ... 8 <i>½</i> d.	3 ... 3 <i>½</i> d.	6 ... 7 <i>½</i> d.

REGISTERED LETTERS.
 Registration provides a secure mode of transmitting Money, Bank Notes, Bank Post Bills, Drafts, &c. On their delivery, the person to whom addressed will be required to sign a receipt. Letters, &c., can be registered on payment of a fee of 2*½* d. in addition to the ordinary rates of postage. Compensation is given for loss or damage of registered letters or packets.

INLAND PARCEL POST.
 The rates of postage, to be prepaid in ordinary postage-stamps, will be for an inland postal parcel of a weight not exceeding 1 lb., 3*½* d.; and 1*½* d. for every succeeding pound.
 Dimensions allowed—length, 3 feet 6 inches; length and girth combined, 6 feet.
 Examples.—A parcel measuring 3 feet 6 inches in its longest dimensions may measure as much as 2 feet 6 inches in girth; or a shorter parcel may be thicker, e.g., if measuring no more than 3 feet in length, it may measure as much as 3 feet in girth, &c., around its thickest part.

FOREIGN PARCEL POST.
 Maximum weight—3 lb., 7 lb., or 11 lb.; rates from 7*½* d. per lb. to 2s., 4*½* d. per lb., according to country. (See "Quarterly Postal Guide.")

TELEGRAPH MESSAGES.
 Twelve words 6*½* d.; every additional word, 4*½* d. Every word telegraphed is charged for, whether in addresses or text.

NOTICES TO CORRESPONDENTS.

INTELLIGENT READERS, do PLEASE NOTE that letters relating to ADVERTISEMENTS, or to the supply of the Paper, should be addressed to the PUBLISHER, and that all communications intended for publication, as well as specimens and plants for naming, should be addressed to the EDITOR. Such communications should be written on one side only of the paper, and sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

ADIANTUM CUNEATUM: *H. H.* The frond is crippled; it is not a sport.
 ADVERTISEMENTS: *J. A. C.* We entirely sympathise with you; but there are considerations, especially financial, which even an Editor cannot afford to overlook, and this is one of them.
 AZALEA MISS JARRETT: *R. D.* The variety Miss C.

Jarrett was shown for the first time, with many other fine varieties new to growers on this side of the Channel, by M. Louis Van Houtte, on May 12, 1885. It is creamy-white, with bright green spots on the upper segments. The flower is fringed at the edge.

BOOKS: *G. N.* See our list of books in this week's issue, p. 10.

BRUGMANSIAS: *M. Freeman.* The plants will do very well stood out in a warm sheltered spot during the summer, and should be again put under glass in September. Plants needing more root room may be potted in April or July. The drainage should be ample, and the compost may consist of loam, one-half; peat, one-quarter; burnt earth or leaf-mould, one-quarter; some coarse sand being added to keep the soil open. During the growing period, and when well rooted, the plants may be watered with some weak manure-water, or a layer of deers' droppings may be spread on the surface of the soil. The object should be to make short-jointed floriferous wood rather than rampant growth, which would scarcely get ripe by the end of the autumn; and consequently cramping the roots in rather small pots or tubs is to be preferred to too much room for the roots to run into. In the period from October to the middle of March the watering should be thorough, and applied only when the ball of earth is moderately dry.

BUILDING AT SOUTH KENSINGTON: *Reader.* According to the terms of the agreement the conservatory and all other buildings fall into the hands of the Commissioners.

CHRYSANTHEMUMS AT 4 FEET IN HEIGHT: *H. H.* Train up a main shoot from the cutting, and in June cut it down to about 4 inches from the soil; select three or four of the shoots that result from that operation, and grow the plant quickly by the aid of good soil and stimulating manure.

DEAD GARDENIAS: *B. Ashton.* We have examined the plants sent, but fail to find anything wrong with the roots, although the stem and crown of the root are dead. The appearances point either to some injurious substance having been poured on the soil near the plants, or to constant watering with very cold water, and which has been allowed always to strike the stem.

LELIA: *J. W. M.* Very bright form of *Lelia* anceps.

NAMES OF FRUITS: *J. R. H.* Blenheim Orange.—*J. F. L., Dublin.* 1, not recognised; 2, Calville St. Sauvour.

NAMES OF PLANTS: *W. Earley.* An Aster, but the specimen is insufficient.—*C. M. S.* *Bougainvillea spectabilis*, probably.—*M. E. B.* *He mionitis palmata*.—*W. S.* *Lelia* anceps.—*G. Humphrey.* The larger spike is a fine one of *Angraecum eburneum*, and the other *A. e. virens*.—*W. J. A. I.* *Cyrtopodium barbatum*; 2, *C. venustum*; 3, *Den-drobium Liniawianum*, generally known in gardens as *D. moniliforme*.—*F. H.* Probably a fragment of some Hymenophyllum.

ORCHID FOLIAGE: *J. B. D.* The leaves have the appearance of being in a too warm temperature and too little ventilation. The punctures made by aphid when the leaf is young will likewise appear as spots later on.

PEACH SHOOTS DROPPING THEIR BUDS: *J. M.* The shoots are imperfectly ripened, and may have cast the buds on the less well ripened wood from that cause, or the border is in a dry state. Peach-tree borders want an abundance of water during autumn and winter if the trees are to be kept in health.

PLANT IN LEAD MINE: *H. A. C. J.* The specimen you send is one of the curious things once called *Rhizomorpha*, and consisting of the threads or hyphae of some fungus, it is impossible to say which.

Correspondents sending plants or fruits to be named, or asking questions demanding time and research for their solution, must not expect to obtain an answer to their enquiries in the current week.

MARKETS.

COVENT GARDEN, January 5.

[We cannot accept any editorial responsibility for the subjoined reports, which, however, are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations represent averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and they fluctuate, not only from day to day, but often several times in one day, and therefore the prices quoted as averages for the past week must not be taken as indicating the particular prices at any particular date, and still less can they be taken as guides to the prices in the coming week. ED.]

No alteration to report this week. *James Webber*, Wholesale Apple Market.

SEEDS.

LONDON: January 4.—Messrs. John Shaw & Sons, seed merchants, of 37, Mark Lane, E.C., report more disposition to purchase Clover seeds. Prices being now low, and stocks generally exceedingly moderate, the outlook of the approaching spring business is regarded as extremely healthy. Clover seeds all round are this week without quotable variation. Higher rates are demanded for Alsike. Fall prices are obtained for Italian Rye grass on account of the lightness of stocks. There is no change to be noted in Canary seed. Hemp seed continues in favour at firmer figures. More money is wanted for Haricot Beans. The Blue Pea trade is slow. Feeding Linseed tends upwards.

CORN.

Averages.—Official statement showing the average price of British corn, imperial measure, in the week ended December 31, 1887:—Wheat, 30s. 9d.; Barley, 29s. 3d.; Oats, 16s. 1d. For the corresponding week in 1886:—Wheat, 36s.; Barley, 25s. 11d.; Oats, 17s. 9d.

FRUIT AND VEGETABLES.

COLUMBIA: January 4.—Moderate supplies of all kinds of fresh vegetables. Trade steady; prices fair. The Potato trade still languid. Quotations:—Cauliflowers, 2s. to 6s. per dozen; Savoy, 3s. to 4s. do.; Brussels Sprouts, 3s. 6d. to 4s. per half-sieve; Spinach, 2s. per sieve; Sprouting Broccoli, 2s. to 2s. 6d. do.; Parsnips, 1s. to 1s. 6d. per score; Celery, 9d. to 1s. per bundle; Seakale, 1s. do.; Greens, 3s. to 4s. per dozen bunches; Turnips, 2s. to 2s. 6d. do.; Carrots, 3s. to 3s. 6d. do.; Beetroots, 1s. 9d. to 2s. do.; Horseradish, 1s. 6d. to 2s. per bundle; Onions (English), 8s. to 9s. per cwt.; foreign, do., 7s. to 8s. per bag of 110 lb.; English cooking Apples, 3s. 6d. to 5s. 6d. per bushel; do. dessert, 4s. 6d. to 7s. 6d. do.; American Apples, 9s. to 10s. per barrel.

STRATFORD: January 3.—Good supplies of all kinds, and fair trade at the following quotations:—Cabbages, 6s. to 8s. per tally; Savoy, 7s. to 9s. do.; Greens, 2s. 6d. to 4s. do.; Turnips, 3s. per dozen bunches; do., 50s. to 50s. per ton; Carrots, household, 35s. to 40s. do.; do., 3s. 6d. per dozen bunches; Parsnips, 6d. to 1s. per score; Mangels, 20s. to 22s. per ton; Swedes, 20s. to 22s. do.; Onions, English, 8s. to 9s. per case; do., Spanish, 8s. to 9s. per case; Apples, English, 3s. to 5s. per bushel; do., American, 15s. per barrel; Brussels Sprouts, 3s. 6d. per sieve; Celery, 6s. to 8s. per dozen rolls; Oranges, 7s. to 9s. per case.

POTATOS.

BOROUGH AND SPITALFIELDS: January 3.—Moderate supply; dull. Quotations:—Regents, 70s. to 110s.; Magnum Bonums, 80s. to 100s.; Hebrons, 80s. to 110s.; Champions, 60s. to 70s. per ton.

COLUMBIA (East London): January 4.—Quotations:—Beanty of Hebron, 80s. to 100s.; Regents, 55s. to 75s.; Magnums, 60s. to 75s.; Champions, 55s. to 65s.; Victorias, 55s. to 70s. per ton.

STRATFORD: January 3.—Quotations:—Magnum, 50s. to 80s.; Regents, 70s. to 100s. per ton.

Imports.—The imports into London last week consisted of 3061 bags from Harlingen, 20 Brussels, 385 Hamburg, 158 boxes Cadiz.

HAY.

Averages.—The following are the averages of the prices obtained at the various metropolitan markets during the past week:—Clover, prime, 80s. to 98s.; inferior, 65s. to 82s.; hay, prime, 70s. to 91s.; inferior, 45s. to 75s.; and straw, 27s. to 40s. per load.

Write for Dr. Voelcker's Report, Pamphlet, Testimonials, and Instructions how to apply

JENSEN'S FISH-POTASH GUANO.

Every grain fertilizes because the Guano is perfectly pure. It is most economical, one part of Manure to 100 parts of soil being ample for garden use.

FISH-POTASH contains Ammonia, Phosphates and Potash in large proportions, which are the principal elements of fertilization.

GUANO—2-lb. Tins, 1s.; in Bags, 7 lbs., 2s.; 14 lbs., 4s.; 28 lbs., 6s. 6d.; 56 lbs., 10s. 6d.; 1 cwt., 16s.; 2 cwt., 30s. Special terms for larger quantities. Analysis guaranteed.

J. JENSEN & CO. LIMITED, 109, Fenchurch Street, London, E.C.

PEAT and SAND.—Light Brown PEAT for Nursery and Greenhouse Work, in four-ton trucks of 10 yards each, at 10s. per yard. In bags at 2s. 6d. per bag. Rhododendro and American Plant Beds, at 15s. per ton. Orchid Peat, 5s. per bag. Fresh SPHAGNUM, 7s. 6d. per bag. SILVER SAND, coarse or fine, 15s. per ton. WALKER AND CO., Farnboro' Station, Hants.

ECONOMY IN THE GARDEN
WOOD & SON WOOD GREEN

A Sterling Novelty for 1888.
"FERTILIZING MOSS."
Intelligent Plant Growers will find this medium for Plant Culture to be eminently useful.
It suits both Soft and Hard-wooded Plants, Ferns, ORCHIDS, and Succulents.
(Of a totally different character to the "Dunessil" Fertilized Moss.)
This is the quality so successfully used by Mr. Roberts at Gunnersbury for Bouvardias and Gloxinias; see *Gardeners' Chronicle*, December 31 and November 12, 1887. Send for full particulars, testimonials, and prices to the Sole Manufacturers,
W. WOOD & SON, Wood Green, LONDON, N. ESTABLISHED 1850.

GARDEN REQUISITES.
TWO PRIZE MEDALS.

Quality, THE BEST in the Market. (All sacks included.)
PEAT, best brown fibrous ... 5s. per sack, 5 sacks for 25s. 6d.
PEAT, best black fibrous ... 4s. 6d. .. 5 sacks for 20s.
PEAT, extra selected Orchid ... 5s. per sack for 35s.
LOAM, PREPARED COMPOST (1s. per bush, 3s. per sack LEAF, or PEAT MOULD ... 4s. (sacks included).
SILVER SAND, coarse, 1s. 6d. per bush, 14s. half-ton, 24s. ton.
RAFFIA FIBRE, best only ... 1s. per lb.
TOBACCO CLOTH, or PAPER ... 8d. lb.; 28 lb., 18s.
SPHAGNUM MOSS, all selected, 3s. per bush, 8s. per sack.
CHUBB'S "PERFECT" FERTILIZER (the Best Food for all kinds of Plants, Flowers, &c.) (Tins, 7lb. 14lb. 28lb. 56lb. 1cwt. Fruits, Vegetables, &c. ... 1/6 3/- 5/- 8/- 14/- 22/-)
CRUSHED BONES, or Bone Dust 1/2 2/- 3/6 6/- 12/-
VIRGIN CORK (Best Quality only) ... 3/- 5/6 10/6 17/-
RUSSIAN MATS, BAMBOO CANES, PERUVIAN GUANO, NITRATE OF SODA, HORTICULTURAL CHARCOAL, &c.
PEAT MOSS LITTER, cheapest and best Bedding for Horses and Cattle, 2/ per ton. Extra large Sample Bales, 6s. each.
COCO-NUT FIBRE REFUSE (by Chubb's special process), sacks, 1s. 3d. each; 10 sacks, 11s.; 15 sacks, 15s.; 20 sacks, 18s.; 30 sacks, 25s.; 40 sacks, 30s.; Truck-load, loose, free on rail, 28s. Limited quantities of G. special quality granulated, in sacks only, 2s. each. Terms, strictly Cash with order. (Bankers, Union Bank of London.)

THOMAS GREEN & SON, LIMITED,

SMITHFIELD IRONWORKS, LEEDS, AND SURREY WORKS, BLACKFRIARS ROAD, LONDON, S.E.,
 HORTICULTURAL ENGINEERS to HER MAJESTY THE QUEEN, call Special Attention to their
**PATENT WROUGHT-IRON MUNICIPAL OR ANGULAR CHAMBERED AND TUBULAR
 HOT-WATER BOILERS,**

And others with **SHELVES**, and Hollow or Ordinary Cast-iron **GRATE BARS**.
SADDLE BOILERS, With WATERWAY BACKS and WELDED BOILERS, any of which are specially adapted for Heating Greenhouses, Conservatories, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c. They are the neatest, cheapest, most effective, and durable of any extant.
The MUNICIPAL and TUBULAR ones are remarkable for their great heating power, slow combustion, and the length of time the fire will burn without requiring attention.
 These Patterns secured the **FIRST and HIGHEST PRIZE a SILVER MEDAL**, at the Royal Horticultural Society's Exhibition, South Kensington, London, June 1, 1881.

The longitudinal section gives a view of the fire-box, water space, flues, &c. The cross section gives a view of the fire-box, water space and V-shaped back. The front elevation shows it set in brickwork, which is necessary for this class of boiler.

Calculated to heat 4-in. piping as follows:—

TESTIMONIALS.

Messrs. THOS. GREEN AND SON, LTD., NORTH STREET, LEEDS.
 Re HEATING APPARATUS. Borough Engineer's Office, Municipal Buildings, Leeds, January 9, 1886.
 GENTLEMEN,—I have great pleasure in bearing testimony to the efficiency and satisfactory working of the Hot-water Heating Apparatus you erected in these public buildings. The buildings are four storeys high, and we have a total length of about 28,000 feet of piping in them, varying in size from 1½ in. to 6 in. diameter, with their connections, &c. The several offices and rooms can all be in operation at one time or separately, and the heat regulated by means of the valves to the temperature required, even in the coldest weather.
 Two of your Patent Municipal Pattern Boilers, No. 4, work the whole of this piping easily, although we have three of them fixed. They are very powerful and economical in the consumption of fuel, and I am pleased to be able to report of them and the apparatus so favourably.
 I am, Gentlemen, yours truly,
 THOS. HEWSON, Borough Engineer.
 Morley House, Bagot, St. Saviour's, Jersey, November 10th, 1886.
 GENTLEMEN,—The large Municipal Boiler which you sent me last year is doing its work satisfactorily; it is heating 5,000 feet of 4-inch pipe in one of my vicarages, and I am quite sure that it has power to work a much greater length, while in cost of fuel it compares favourably with my other Boilers.
 I have now five of your Boilers in use, and I cannot speak too well of their heating powers, or their comparatively small consumption of fuel.
 Yours faithfully,
 (Signed) G. W. BASHFORD.
AND HUNDREDS OF OTHER REFERENCES CAN BE GIVEN IF REQUIRED.

CONTRACTORS TO HER MAJESTY'S WAR DEPARTMENT.

THE THAMES BANK IRON COMPANY,

UPPER GROUND STREET, LONDON, S.E.

Seed Trade.

WANTED, a JUNIOR ASSISTANT.—Apply, with particulars, to DICKSON AND ROBINSON, Seed Merchants, Manchester.

WANT PLACES.

NOTICE TO ADVERTISERS.—In many instances Remittances in Payment of Repeat Advertisements are received without name, address, or anything beyond the postmark, on envelope by which to identify the sender; this in all cases causes a very great deal of trouble, and frequently the sender cannot be identified at all. Advertisers are requested when Remitting to give their Names and Addresses, and also a Reference to the Advertisement which they wish repeated.

B. S. WILLIAMS begs to intimate that he has at present in the Nursery and upon his Register some excellent Men, competent either to fill the situation of **HEAD GARDENER, BAILIFF, FOREMAN, or JOURNEYMAN.** Ladies and Gentlemen requiring any of the above will please send full particulars, when the best selections for the different capacities will be made.—Holloway, N.

HOLLOWAY'S OINTMENT and PILLS are the best, the cheapest, and the most popular remedies. At all seasons and under all circumstances they may be used with safety and with the certainty of doing good. Eruptions, rashes, and all descriptions of skin diseases, sores, ulcerations, and burns are presently benefited and a timely cured by these healing, soothing, and purifying medicaments. The Ointment rubbed upon the abdomen checks all tendency to irritation of the bowels, and averts dysentery and other disorders of the intestines. Pimples, blotches, inflammation of the skin, muscular pains, neuralgic affections, and enlarged glands can be effectively overcome by using Holloway's remedies according to the "instructions" accompanying each packet.

CHARLES SHARPE & CO.'S
SPECIALTIES, 1887-8.

SHARPE'S PEA. 3s. 6d. per pkt.	VICTORY. First-class Certificate, R.H.S., 1886. This magnificent variety surpasses everything we have ever seen. The habit of the plant is vigorous and much branched. Pods produced in pairs, occasionally three together, well filled with large Peas, ten to eleven, of extra fine flavour, and deep green colour when cooked. Height 2 feet.
SHARPE'S PEA. 2s. 6d. per ½ pint.	EMPRESS. An improved Ne Plus Ultra. Deep green pods of immense size, containing ten or more fine large deep green Peas, of exquisite flavour. Height 5 feet.
SHARPE'S PEA. 3s. per pint pkt. 1s. 6d. per ½ pint packet.	QUEEN. A grand Blue Marrow; height 2 feet. Pods large, deep green, with large, green, deliciously flavoured Peas. It is so continuous a cropper that a constant supply may be maintained by it alone after the first crop is ready.
SHARPE'S PEA. 1s. 6d. per pint packet. 1s. per ½ pt. pkt.	SIR F. A. MILBANK. A magnificent, large, Blue Wrinkled Marrow. Peas extra large—deep green. Very hardy. Height 5 feet.
SHARPE'S PEA. 1s. 6d. per pint packet. 1s. per ½ pt. pkt.	TRIUMPH. A fine Dwarf Blue Wrinkled Marrow, fine flavoured and heavy cropper—sixty-nine Pods, with nine to eleven Peas in each, gathered from one plant.
SHARPE'S PEA. 2s. 6d. per quart. 1s. 3d. per pint.	PARAGON. Hardest and earliest large Wrinkled Marrow. Successive crops can be had for four months. <i>First-class Certificate R.H.S., 1884.</i>
SHARPE'S POTATO. 1s. per pound.	STANDARD. The finest round Potato ever sent out. An extraordinary cropper, flesh white, mealy, and of excellent flavour; handsome large flattish-round tubers.

For full description see Advertisements in the Horticultural Papers; or

Post-free on application.

CHARLES SHARPE & CO., SLEAFORD.

TRADE PRICES ON APPLICATION.

CHARLES SHARPE & CO.'S
SPECIALTIES, 1887-8.

SHARPE'S POTATO. 6d. per pound.	VICTOR. The earliest, quickest, and most productive kind for forcing or early planting—ready for table in from six to eight weeks.
SHARPE'S POTATO. 2s. 6d. per stone.	DUKE OF ALBANY. Most valuable main crop variety—good to use from July to March.
SHARPE'S BROCCOLI. 2s. 6d. per pkt.	MONARCH. Firm clear heads of great weight, large; pure white: often 12 to 15 inches in diameter, and attaining prices in the Market up to 9s. per dozen. Season, March and April.
SHARPE'S BROCCOLI. 1s. per packet.	SELECTED WINTER. An improvement upon Osborn's Dwarf, with firm, pure white heads. Ready for use from the middle of November forward.
SHARPE'S BEAN. 1s. per pint.	CONQUEROR. The longest-podded variety known. Pods often 16 to 18 inches long. Fine for Exhibition.
SHARPE'S CUCUMBER. 2s. per packet.	EPICUREAN. The most prolific, earliest, deepest in colour, and finest in flavour of any variety grown. Fruit long and very handsome. It is simply perfection.
SHARPE'S BEET. 1s. per packet.	EMPEROR. The finest of the glossy-leaved varieties used for bedding. Leaves metallic in appearance and very deep in colour. The root is deep red, without rings, and very rich in flavour.
SHARPE'S TOMATO. 1s. per packet.	ECLIPSE. A remarkably prolific variety. Fruit globular, smooth, growing in large clusters at every joint; exquisite flavour, colour bright cherry-red.
SHARPE'S ONION. 1s. per packet.	PRIZE WHITE SPANISH. The best type of the Banbury section of Onions.

A 92-Page
CATALOGUE,

embellished with
109 ENGRAVINGS,
(many of which, like the flowers they illustrate, are original), consisting exclusively of

FLOWER SEEDS.

I have much pleasure in announcing that my New CATALOGUE of Flower Seeds is now ready, and has been Posted to all Customers, who will doubtless welcome it as a valuable Catalogue for reference, and to whom, I am sure, it will prove especially instructive and attractive. Considering that its pages are devoted to Flower Seeds only, it is perhaps not too much to claim, that it is the LARGEST CATALOGUE of these ever published, and includes in its varied columns very many species and varieties, which can be procured from Tottenham only; and while desirous to introduce a large amount of stuff not generally known, I have—as is my wont—had due and proper regard to the fact, that as a rule buyers do not care for specialties unless they are distinct and effective. All the novelties and varieties appearing in this Catalogue claim such a distinction.

Copies may be had Gratis and Post-free upon application. Kindly mention this Paper when writing for Catalogue.

THOMAS S. WARE,
Hale Farm Nurseries,
TOTTENHAM, LONDON.

1s. per packet; enclose 13 stamps which will ensure a packet being sent. Write for CATALOGUE of Novelties to R. GILBERT, Burghley, Stamford.

NEW MELON,
"TEMPLENEWSAM HYBRID."

The above new and distinct variety was raised by Mr. Dawes, Gardener to the Hon. Mrs. Meynell-Ingram, Templenewsam, and is the result of a cross between the well-known varieties, HERO OF LOCKINGE and READ'S SCARLET. It was awarded a First-class Certificate at the Spring Exhibition of the Manchester Botanical Society, 1887, and it has on several occasions been locally exhibited, never failing to win golden opinions from competent judges.

TEMPLENEWSAM HYBRID is a very handsome oval-shaped Melon, with a rich golden-yellow skin, beautifully netted. The flesh is white, deep, rich and melting to the rind, and the flavour is all that can be desired. It is early, arriving quickly at maturity, is of free growth, an excellent setter, produces fruits averaging from 4 to 4½ lb. each, and when fully ripe remains a long time fit for use.

Mr. COLEMAN, *The Gardens, Eastnor Castle*, says:—"A good size, shape oval, skin bright golden, and beautifully netted. Flesh white, deep, and melting quite through to the rind. Flavour excellent, reminding me of my own Eastnor Castle."

Mr. ROBERTS, *The Gardens, Prestwold Hall*, says:—"The Seedling Melon is perfect in shape, nicely netted, with a thick soft flesh of a rich and excellent flavour. I consider it quite distinct."

Mr. CHUCK, *The Gardens, Erosworth Hall*, says:—"Your Seedling Melon I consider a first-class variety, and worthy of extensive cultivation."

Many other thoroughly practical Gardeners have seen this variety, and verify by their opinions the high characteristics that we claim for it, and with which we have great pleasure in bringing it under public notice.

Price, 2s. 6d. per Sealed Packet, post-free.

CHARLES SHARPE & CO.'S
SPECIALTIES, 1887-8.

SHARPE'S PEA. 3s. 6d. per pkt.	VICTORY. First-class Certificate, R.H.S., 1886. This magnificent variety surpasses everything we have ever seen. The habit of the plant is vigorous and much branched. Pods produced in pairs, occasionally three together, well filled with large Peas, ten to eleven, of extra fine flavour, and deep green colour when cooked. Height 2 feet.
SHARPE'S PEA. 2s. 6d. per ½ pint.	EMPRESS. An improved No Plus Ultra. Deep green pods of immense size, containing ten or more fine large deep green Peas, of exquisite flavour. Height 5 feet.
SHARPE'S PEA. 3s. per pint pkt. 1s. 6d. per ½ pint packet.	QUEEN. A grand Blue Marrow; height 2 feet. Pods large, deep green, with large, green, deliciously flavoured Peas. It is so continuous a cropper that a constant supply may be maintained by it alone after the first crop is ready.
SHARPE'S PEA. 1s. 6d. per pint packet. 1s. per ½ pt. pkt.	SIR F. A. MILBANK. A magnificent, large, Blue Wrinkled Marrow. Peas extra large—deep green. Very hardy. Height 5 feet.
SHARPE'S PEA. 1s. 6d. per pint packet. 1s. per ½ pt. pkt.	TRIUMPH. A fine Dwarf Blue Wrinkled Marrow, fine flavoured and heavy cropper—sixty-nine Pods, with nine to eleven Peas in each, gathered from one plant.
SHARPE'S PEA. 2s. 6d. per quart. 1s. 3d. per pint.	PARAGON. Hardest and earliest large Wrinkled Marrow. Successive crops can be had for four months. <i>First-class Certificate R.H.S., 1884.</i>
SHARPE'S POTATO. 1s. per pound.	STANDARD. The finest round Potato ever sent out. An extraordinary cropper, flesh white, mealy, and of excellent flavour; handsome large flattish-round tubers.

For full description see Advertisements in the Horticultural Papers; or

CHARLES SHARPE & CO.'S
SPECIALTIES, 1887-8.

SHARPE'S POTATO. 6d. per pound.	VICTOR. The earliest, quickest, and most productive kind for forcing or early planting—ready for table in from six to eight weeks.
SHARPE'S POTATO. 2s. 6d. per stone.	DUKE OF ALBANY. Most valuable main crop variety—good to use from July to March.
SHARPE'S BROCCOLI. 2s. 6d. per pkt.	MONARCH. Firm clear heads of great weight, large; pure white; often 12 to 15 inches in diameter, and attaining prices in the Market up to 9s. per dozen. Season, March and April.
SHARPE'S BROCCOLI. 1s. per packet.	SELECTED WINTER. An improvement upon Oshorn's Dwarf, with firm, pure white heads. Ready for use from the middle of November forward.
SHARPE'S BEAN. 1s. per pint.	CONQUEROR. The longest-podded variety known. Pods often 16 to 18 inches long. Fine for Exhibition.
SHARPE'S CUCUMBER. 2s. per packet.	EPICUREAN. The most prolific, earliest, deepest in colour, and finest in flavour of any variety grown. Fruit long and very handsome. It is simply perfection.
SHARPE'S BEET. 1s. per packet.	EMPEROR. The finest of the glossy-leaved varieties used for bedding. Leaves metallic in appearance and very deep in colour. The root is deep red, without rings, and very rich in flavour.
SHARPE'S TOMATO. 1s. per packet.	ECLIPSE. A remarkably prolific variety. Fruit globular, smooth, growing in large clusters at every joint; exquisite flavour, colour bright cherry-red.
SHARPE'S ONION. 1s. per packet.	PRIZE WHITE SPANISH. The best type of the Banbury section of Onions.

ECKFORD'S CULINARY PEA, "FAME."

First-class Certificate Royal Horticultural Society.

A Main Crop Wrinkled Pea, growing 4 feet, producing profusely deep green, square ended, well filled pods. An improved Ne Plus Ultra, coming into use much earlier than the fine old variety of that name. Flavour exquisite.

In sealed half-pint packets, 2s. 6d. each.

ECKFORD'S CULINARY PEA, "SHROPSHIRE HERO."

First-class Certificate Royal Horticultural Society.

A Wrinkled Pea, of robust growth. Height, 2½ feet. Second early. Produces abundantly long, square, handsome, well filled pods; well adapted for market growers. Flavour exquisite. A great acquisition.

In sealed half-pint packets, 2s. 6d. each.

ECKFORD'S SWEET PEA, "SPLENDOUR."

First-class Certificate Royal Horticultural Society.

Colour, rich bright pinkish-rose, shaded with crimson. Flower, large and of the finest form. A superbly distinct variety. In sealed packets of 25 seeds, 1s. 6d. each.

ECKFORD'S SWEET PEA, "APPLE BLOSSOM."

The standard's bright pinkish-rose, the wings blush. A beautiful Apple Blossom. Very pretty and distinct.

In sealed packets of 25 seeds, 1s. 6d. each.

ECKFORD'S MIXED SWEET PEAS.

Special strain, saved from choice unnamed varieties of Mr. Eckford's raising, and includes many of great merit.

In sealed packets of 25 seeds, 1s. each.

NEW JANUARY FLOWERING CHRYSANTHEMUM, GOVERNOR OF GUERNSEY.

Awarded a First-class Certificate by the
NATIONAL CHRYSANTHEMUM SOCIETY
at the late Show, held on Wednesday, January 11, 1888.

I have very much pleasure in introducing to the notice of both Trade and Retail Buyers (especially the former) of Chrysanthemums, an invaluable new January flowering variety, which, I feel assured, is destined to occupy quite a leading position amongst the yellow-flowering varieties, and must become the best yellow sort for late cutting. Those who saw the flowers exhibited at the recent show will hear me out in this assertion. Of its lateness there can be no question, and it retains its good character as a well-formed full-coloured flower to the latest blooms.

The colour is of a rich distinct buttery yellow, distinct in every way from all other late-flowering yellow varieties; in form it partakes of the style of the Japanese to a considerable extent, although it exhibits considerable tendencies to incurve the petals before the flowers are fully developed.

Flowers have been shown to several of our best Chrysanthemum judges, who agree that, as a decorative variety, either upon the plants, and especially for cutting purposes, very late in the season, it must prove a great acquisition. It has a good, very strong habit, without being tall and unwieldy, having marvellously strong, stout, wiry stems, the flowers standing on this account bolt upright upon them.

As my stock is limited, and anticipating a very considerable demand for it, my flowering plants have been cut down for stock purposes, so that I am now unable to show any more blooms, or would have been only too happy to post a specimen flower to all applicants.

A well-executed and very faithfully coloured plate is, however, in course of preparation, a copy of which I shall be very happy to send to anyone who may be pleased to apply for it.

Plants ready in April, 2s. 6d. each, 24s. per dozen.
Trade prices upon application.

My NEW CATALOGUE OF CHRYSANTHEMUMS, including all the new varieties of present and last season, is in course of preparation, and will be posted free upon application.

THOMAS S. WARE,
HALE FARM NURSERIES,
TOTTENHAM, LONDON.

"THE DANIELS" Is the coming POTATO.

A cross between the White Elephant and Magnum Bonum, having the unexcelled qualities of both. Ready to lift same time as White Elephant. An immense cropper, and of splendid table quality. All Potato growers should try it.

Price per peck, 3s. 8d.; per bushel, 12s. 6d.;
per sack, 30s.

From Mr. J. ERR, Broom Park, Clebury Mortimer, Oct. 29:—"The seed Potatoes, The Daniels, I bought of you last spring have turned out remarkably well in quantity as well as quality; I had 286 lb. from 7 lb.; not one diseased."

From Mr. E. PITT, Ventnor, I.W.:—"From 2 lb. of your new Potato, The Daniels, I have raised 213 lb., of splendid quality."

A CHANGE OF SEED ALWAYS PAYS.

Before ordering your supply seed for Daniels' Illustrated Potato Catalogue, containing valuable hints on the Potato, with descriptions of nearly 200 kinds, and the latest Novelties. Gratis and Post-free to all applicants.

SATURDAY, JANUARY 14, 1888.

NASH COURT.

[SEE SUPPLEMENTARY SHEET.]

BY the side of the old road leading from London to Dover, about three miles beyond the little town of Faversham in the direction of Canterbury, is situated Nash Court. Looking from the hall door across the lawn, the visitor gets a delightful prospect over the neighbouring village of Boughton—over fields and copses and Hop gardens, with square-towered churches interspersed, till the vision is stopped by a fine wood-clad range of hills, stretching horizontally directly in front of the observer, sloping down to the sparkling sea near Whitstable on the one side, and trending inland in the other direction.

This range is of London clay, capped in places by more recent tertiary sands, and itself resting on sands overlying the chalk, which is the bed of this part of Kent, however much it be overlain by other deposits. To the left, not far off, are salt marshes bordering the creek—muddy, certainly, at low water, but offering a perfect paradise for the botanist, and, indeed, for the naturalist generally. Our business lies not in that quarter, however, nor is it concerned with Chaucer, although, standing on the garden terrace looking on to the Blean Woods, and with that long white strip of a road which mounts over Boughton Hill straight in front, we cannot avoid a passing thought of the merry, motley company that Chaucer makes to pass over that very hill, if not by that very road,

"—to wher ther stont a litel town,
Which that cleped is Bob-up-and-down,
Under the Ble in Caunterbury way."

that "litel town" being the present Harbledown, from the last of whose many hills must have burst upon their view the Cathedral towers of Canterbury, the shrine of the martyred bishop—

the goal of their wanderings. There was no such straight road then; there were no Hop gardens; the square-towered churches did not exist—at least in their present form; and the Cathedral must have worn a very different aspect from that which now delights the traveller. Wild animals, including two-footed ones, lurked in the woods of Ble in those days; the road was steep and toilsome; even now the railway engineers have evaded the difficulty of surmounting the hill or tunneling through it, and swerved to the right some miles out of the direct line in order to reach the old city.

Who was the lord of Nash Court in those days we do not know; certainly the present red-brick mansion, now occupied by Mrs. Lade, is many centuries younger, and yet the general features of the country—the hills, the woods, the marshes, the glistening sea—cannot have altered greatly in appearance, and those who stood where Nash Court now is must have seen the same beautiful prospect as we do now, though they probably did not appreciate it as we do. Times have changed, and we have the advantage of a keener sense of appreciation of the beauties of Nature. On the lawn and its belting shrubberies are specimen Conifers, and Hollies, and Rhododendrons, and representatives of the manifold wealth of tree and shrub of which we have the benefit, but which were not dreamed of by our forefathers. True there is an avenue of gnarled, deep furrowed Sweet Chestnuts; but old as they are—and they count their years by centuries—they can hardly have been gazed on by the Canterbury pilgrims of Chaucer's time. To-day (January 6) the distant woods are all aglow in the sunshine. We are not near enough to see what are the trees (probably Oaks) which are so resplendent; but as we turn from the one side, where are the deciduous trees with their winter beauty made glorious by the sun, to the rich greens, shining bronzes and golden yellows of the evergreens on the other, we begin to think that our forefathers were after all not so very badly off, provided they had—as no doubt they had—the occasional enjoyment of sunny days even in mid-winter.

Shelter is needed at Nash Court. Not far off, as has been said, is the sea, but the fiercest winds come from the opposite quarter, and so we find provided belts of Black Austrian Pines, deep green in colour, with silvery buds projecting from the tips of their branches—dense and massive is their foliage, rich their colour and warm their shelter. Of all the Pines this is perhaps the most useful as a shelter, for none is so hardy. What value its timber may have, we do not know, but if it be as good as that of its near relative the Corsican, there cannot be much to complain of.

Protected by these comfortable-looking Pines is a selection of the best of the Californian Conifers—the Japanese, which are quite as hardy, if not harder, have not reached these regions yet. *Pinus insignis* is of as lovely a shade of green here as it always is, and *Cupressus macrocarpa* is not far behind it. Were it not for these sheltering Pines it is doubtful whether these two species could so long have survived the Kentish winters, which are not gentle just here, *Abies Pinsapo* does well, and *A. lasiocarpa* is represented by several thriving specimens, one with very pendulous branches. There is a prejudice in certain quarters against golden Conifers, but no one, we venture to say, who could have seen on this bright day the brilliant colours of the golden Lawson's Cypress, or the rich bronze of *Biota elegantissima*, backed up and framed by dark evergreens, but would have had his prejudices shaken, and would at least have admitted that the golden Hollies had worthy rivals. Specimen Conifers of large size are dotted about on the lawn and pleasure-ground, but they have been mauled by the wind, and were suffering in consequence, when it occurred to Mr. Humphreys, the gardener, to allow sheep to graze under them, and the rich food so obtained has benefited the trees at root as well as at top, though their graceful form has been spoilt beyond recovery. An avenue

of Araucarias is also very striking; the trees have done well, and grown symmetrically, as if they were well chosen in the beginning, and, better still, planted with sufficient care. Roses occupy a post of honour on the lawn—a herbaceous border between two sheltering hedges, flower-beds and carpet-beds, all these are to be seen at Nash Court, but the present is not the time to see them. It is curious to note how easy it is to conjure up these things, and to frame a picture of what the garden must be in the full glow of summer—what richness of floral colouring the sea air must give, and so forth. It is not quite so easy to reconstruct in imagination the other features of a garden. A true and accurate picture of the garden with its summer occupants can be called up on the instant, but when it comes to things with more individuality and character, showing traces of their history in their features, and giving evidence of the changeful circumstances against which they have had to contend, then a considerably greater draft on the bank of taste and knowledge is demanded to secure a faithful image.

In an establishment like this flowers are in demand the year through, and what the outer air denies must be furnished by the gardener with the aids and appliances at his command, and so we find here a Eucharis-house well filled with fine samples of the chaste flowers of this lovely Amazonian bulb. In company with them are numerous plants of the double white *Bouvardia* Alfred Neuner—excellent for cutting. In other houses are *Poinsettias*, *Gardenias*, in pots, fine plants, though less than two years old; *Cinerarias*, already showing for bloom; *Azaleas*, *Cyclamens*, *Libonias*, a *Vallota*, of which we shall have more to say later on; decorative plants, such as *Anthuriums*, *Dracenas*, and *Crotons*, and a few *Orchids*. Besides, there are Pine-stoves and *Pinepits*, *Peach-houses*, and *vineries*, of which there is not much to be said at this season.

The conservatory is a light square structure forming the centre of a range. In the centre is a fine *Latania*, flanked on one side by a *Kentia Mooreana*, said to be one of the two only existent in the country, and on the other by another specimen of the same genus. *Camellias* occupy the side borders, and both leaves and flowers testify to their careful culture. *Lapagerias*, white and rose, trained on trellises, yield a profusion of blossom, pre-eminent in this respect being the large-flowered, large-leaved variety, known as the Nash Court variety, which was certificated at South Kensington on October 14, 1884, and whose good qualities have made the name of Nash Court familiar to many to whom it was previously unknown. A peep down into the dim recesses of the stokehole reveals two *Trentham* boilers, one in full work, the other a reserve in case of need. The sight is satisfactory and suggestive, but not exactly æsthetic—for that you must look elsewhere. A few steps, and we come to an ordinary-looking door in an ordinary-looking wall; the door is opened suddenly, the subtle gardener has prepared a surprise—and a surprise it is in the beginning of January to see such a picture of verdure, such a wealth of elegant form—so much stateliness of aspect combined with so much elegance of "habit"—as are comprised within the fernery into which we are now ushered. It is an oblong structure, some 80 by 33 feet, and 19 feet high, with a ridge-and-furrow roof, shaded in summer by a composition of the nature of "Summer Cloud." The back wall is wholly of brick, while the other walls are of brick for half or more of their height, and then of glass. Graceful pendants of *Nephrolepis* hang from the walls, and as if the Ferns themselves did not furnish sufficient covering a background of *Ficus repens* is provided. Pillars of iron support the roof at intervals, each pillar a support for climbing *Asparagus* and *Lygodium*. Pockets hung on to the pillars serve to grow endless smaller Ferns. A lakelet, edged with *Selaginella apoda*, winds a sinuous, but still too formal, course through the building, and is crossed about the centre by a rustic arch densely clothed with *Adiantums*. Headlands and peninsulas of rock thickly draped with Ferns jut out into the house, and on their slopes big

Cyatheas, *Alsophilas* and *Dicksonias*, as well as *Palms* like *Seaforthias*, rear their feathery plumes above a tangled undergrowth amid which are sunk pockets for the reception of foliage *Begonias*, *Dracenas*, *Caladiums*, and other plants, which serve to vary the monotony of aspect which Ferns alone might have and ensure a variety in colour lacking in Ferns by themselves. To mention the Ferns in this rich collection would be to write a catalogue. In addition to the handsome Tree Ferns already alluded to, there are fine clumps of the crested variety of that most graceful Fern, *Microlepia hirsuta*. There is a profusion of species of *Adiantum*, comprising *cuneatum*, *capillus veneris*, *terreum gracillimum*, while *A. Williamsi* and *A. Flemingi*, a variety of *concinnum*, are highly spoken of; but we will not begin enumeration, or we should soon weary our readers. Let it suffice to say that the collection is very rich in species and varieties, and, better still, they are in admirable health. Though scarcely a vacant space or uncovered piece of rock is to be seen, the plants are not unduly crowded; each looks well developed, as if it had room to expand without interfering with its neighbour's right, and the whole house has the appearance which good cultivation and judicious management alone can give.

It is always satisfactory to be able to cite confirmatory evidence of one's statements, and we think no slight confirmation is given by the supplementary illustration in our present issue. An inspection of that photograph will, we believe, ensure credence to our statement, that not only the fernery, but that the whole place does credit to the gardener to whom its charge is entrusted.

VANDA CÆRULEA.

THE subject of our illustration (see p. 41) is certainly one of the most beautiful of Orchids, its lovely flowers exhibit such charming shades of blue, rendered the more clear and bright by reason of their being displayed on the white ground of the flower, that it is difficult to conceive a worthier example of a plant for general cultivation; but it must be said that while a few growers cultivate it successfully for a number of years, others succeed in getting it to thrive for a time, when "spot" and other evidences of degeneration step in; while a third class of growers never succeed in growing or flowering it at all satisfactorily. The fact that *V. cœrulea* is of free growth with some, points to the fact that its bad condition in the hands of others is from no peculiarity of its own, but is due to a want of proper treatment.

Generally speaking, too much heat, too much sunlight, too little air, and drying off during a portion of the year, are the sources of ill-health with this plant. Most of those who grow it will keep it in a rather cool temperature (50°–60° Fahr.), suspended near the glass of the roof in a well-ventilated position, but out of reach of cold currents of air from any of the ventilators; and more than one who had failed with it under warm treatment have succeeded with it on removal to the cool-house.

Sir J. D. Hooker records the plant in the Khasian Mountains, at an altitude of 3000–4000 feet, and Griffiths found it on trees of *Gordonia* in Oak and Pine forests at a height of 2500 feet; it will therefore readily be seen that *V. cœrulea* cannot be a hothouse plant. Further, it is known of it that the plants are sheltered by the growth of the trees they are attached to, the points only and flower-stems peering through, generally speaking.

The climatal conditions under which this plant grows naturally are well explained in an interesting communication from Mr. C. B. Clarke in our number for January 15, 1887, p. 77. Fog, wet, and night frosts, with at no time a very high temperature, are what this plant endures. This is not exactly the *regime* to which it is subjected here, nevertheless, Mr. Kimball, as shown in our woodcut, evidently contrives to do it well.

NEW OR NOTEWORTHY PLANTS.

LÆLIA GOULDIANA, n. sp. or n. hyb.?

Finis coronat opus! The last Orchid of the year 1887 was this. It opened its grand flowers on both sides of the Atlantic at once. I got remarkably fresh, fine inflorescences (one of two, one of five flowers) from Mr. Sander, and two three-flowered ones from Messrs. Siebrecht & Wadley, New York. Our American correspondents desired that the plant

purple, and exceedingly difficult to match on paper. The lip is trifid. The side-laciniae are very long, blunt, antrorse, the mid-lacinia cuneato-obovate retuse; with an apiculus in the centre. The three lamellæ of the disc are continued on the superior part of the mid-lacinia. The side-lacinia are white with light purple edges; the mid-lacinia is of the darkest, warmest purple, only white at the base, with fine, strong purple nerves and spots extrorse on the disc. Keels spotted with purple, and with similar lines. Column white, with numerous purple spots.

grad colours. It might be luckier to avoid the parentage of *L. albida* since the flowers are as large in our plant as in a good *L. autumnalis*. Those fine lineaments at the base of the side of the disc are usually found in the last mentioned species, though not so fine by far. This makes us think of *L. anceps*.

And why is it not a species, when the nearest allies have such very slight characters? And as a species may have a very wide area, perhaps this *L. Gouldiana* may be a variety of *L. Crawshayana*.

FIG. 8.—GROUP OF VANDA COerulea AT MR. W. S. KIMBALL'S, ROCHESTER, N.Y. (SEE P. 40.)

might be dedicated to their celebrity, Mr. Jay Gould, and that has accordingly been done.

The bulbs are two-leaved, fusiform, nearly 4 inches long, markedly furrowed, and costate. Leaves cuneate, ligulate, acute, very strong, nearly a foot long, but sometimes much shorter. The slender purple peduncle exceeds a foot in length. There are a few distant sheaths, and the spathaceous bracts attain nearly to half the length of the stalked ovaries. Those organs are shining, full of asperities, and a few furfuraceous, blackish masses stand on the base of the outside of the sepals. Both sepals, and the much broader petals, have a curious character by their being more strongly acuminate than is the case in any of the species near it. The colour is wonderfully warm

It is very near Mr. De Crawshay's *Lælia*. The ovaries are distinct, the side lacinia of the lip much longer, the keels are distinct, and the just named plant lacks the retuse apex of the lip. It might be the inverted hybrid. It is also very near *Lælia autumnalis* itself, but the shape of the sepals, petals, and lip, and the colours are remarkably distinct. Usually, indeed, *Lælia autumnalis* has much broader leaves and much shorter bracts. Yet it occurs with narrow leaves and I have a fine raceme with similar long bracts in my herbarium of *L. autumnalis* "tip-top."

If it is a hybrid, as *L. Crawshayana* may also be, you must think of *L. autumnalis*, and perhaps, of *L. anceps* as possible parents; by reason of the

After all—it is very easy to conjecture but very difficult, nay, impossible, to give evidence what it is. Let us give up scientific guessing, and admire the beauty. *Finis coronat opus.* H. G. Rehb., f.

BONATEA SPECIOSA.

A plant of this remarkable and most interesting Orchid is now flowering in the Kew collection. The species is frequently mentioned by Darwin in his book on the *Fertilisation of Orchids*, and he writes at p. 334, "I should doubt whether any member of the orchidean order has been more profoundly modified in its whole structure than *Bonatea speciosa*." The genus, which is South African and nearly allied to *Habenaria*, contains but two or three species. The

one under notice was introduced in 1820. Its flowers measure $1\frac{1}{2}$ inch in depth and somewhat less in diameter; and although by no means showy, as we now regard Orchids, they attract attention by their singular shape. The arrangement of the parts of the flower is so different from that of most Orchids that it requires careful dissection to understand it. The sepals are green, the two lateral ones subfalcate and acuminate, while the upper one, which covers and is apparently intended to protect the pollinia, assumes the shape of a hood or helmet. The petals are bipartite, the green inner segments standing erect within the helmet-shaped sepal, and the outer segments, which are linear in shape, and white with green points, are united for a short distance to the upper surface of the lip, and take a direction almost at right angles to the other half. The labellum itself is divided into three long, narrow segments, and develops a spur about $1\frac{1}{2}$ inch in length. Just within the outer portions of the petals are two white, petaloid, cylindrical processes, half-an-inch in length, at the apices of which are the bright and viscid stigmatic surfaces.

A remarkable provision to secure the removal of the pollinia by an insect in search of nectar is pointed out by Mr. Trimen in a note on this species in vol. ix. of the *Journal of the Linnæan Society*. There is placed in the centre of the labellum, just in front of the opening of the nectary (spur) a little projection about one-eighth of an inch in length; this compels the insect to thrust in its proboscis from either side, and the discs of the pollinia are so placed that by doing so the attachment of one or the other is secured. Mr. Trimen observes that he found no nectar in the flowers of the plant he inspected; it may therefore be interesting to state, that on examining the plant at Kew the spurs were found to be half filled.

The flower is remarkable also for the unusual cohesion of its parts to the labellum. The outer segments of the petals, the stigmatic processes mentioned above, and the two lower sepals (although belonging, morphologically, to another whorl) are all united to the labellum.

The flowers are arranged in an erect spike, which terminates a stem from 1 to 2 feet high, clothed almost to the base with dark green, glabrous, oblong leaves. The culture of the plant is easy; it grows with great freedom if potted in sandy loam and peat, its large fleshy tubers filling the bottom of the pot. It may be grown during summer in the cool-house, but when showing its flowers it should be removed to a warmer position. *W. B.*

CYPRIPEDIUM PITCHERIANUM, *Manda*, n. sp.—Philip-
pine Islands.

"Roots thick, dark, and downy; leaves acute, 5 inches long and $2\frac{1}{2}$ inch wide, coriaceous, green tessellated with irregular darker spots, smooth on both sides but slightly incised at the edges; scape over a foot high, purplish and downy; bract 1 inch long, green; ovary $1\frac{3}{4}$ inch long, green and grooved, remarkably bent downwards. The dorsal sepal is over 2 inches long and nearly 2 wide, acuminate, slightly revolute, whitish with bright green veins, and beset with many black and dark purple spots, some running in lines, while others are scattered irregularly, covering nearly the whole sepal; the lower sepal is $1\frac{1}{2}$ inch long and $\frac{3}{4}$ inch wide, whitish with broader green veins; petals deflexed, $2\frac{1}{2}$ inches long by $\frac{3}{4}$ inch wide, whitish changing to purple towards the ends, and with several bright green veins running through; both edges are beset with black warts and hairs, while the inner part is covered with many large and smaller black spots; the lip is 2 inches long and uniformly $\frac{3}{4}$ inch broad, roundish, light purple with darker veins, and the underside is whitish green, while the inside is most beautifully studded with dark purple on a yellowish ground; the staminode is purplish, horseshoe shaped, with points incurved inside nearly touching each other, differing thus from the rest of the *barbatum* group, in which this plant may be classed.

"The distinct features of this plant are the upper

sepal spotted and the curious ovary that bends downward, on which the flower is suspended, giving it thus quite a novel appearance, by which it is easily recognised. It is certainly one of the most beautiful Cyripeds, and flowering at this time of the year, it will be a welcome addition to the already many existing kinds. Unfortunately this is an unique plant at present, I having received it among other plants coming from the East Indies. The plant is growing well in a warm house with plenty of light and moisture, potted in peat, sphagnum and potsherds. It gives me great pleasure to name this plant after James R. Pitcher, Esq., of Short Hills, N.J., who is a great lover of this genus, and the happy owner of one of the finest collections of this class of plants." *W. A. Manda*, in "*American Florist*."

ROSES.

SOME NEGLECTED ROSES.

THE MOSS ROSE.—There are two extremes into which persons are liable in these days to run with regard to the Rose—one is to look at every Rose in the light of the exhibition table and carefully to discard from the garden every flower that does not come up to the exhibition standard, as, in the height of the bedding-out mania, persons were wont when a new plant was advertised to inquire, Will it do for bedding?—the other extreme is to go into ecstasies over those "dear old-fashioned Roses in which we used to delight in our young days. We don't want those great Marie Baumanns, or Charles Lefebvre; so stiff and formal; let us have the dear old Roses"—although, put them in the witness-box and ask them what they mean, it is a great chance if you get beyond "Oh! that delicious Cabbage Rose, you know"—it goes generally no further.

It is well to avoid extremes in this as in other things—to remember that the best of our exhibition Roses are often the best for the decoration of the garden, and that the time of beauty for the neglected Roses is after all a brief one, and so disappointment arising from exaggerated hopes will be avoided. I have lived a good many years in the world, and have been fond of flowers ever since I can remember (perhaps I inherited it from my Huguenot forefathers), but I never until the other day met with any one who did not admire a Moss Rose—in the bud, of course; but I did meet one, and that a lady, who told me that she saw no beauty in it. To me there is nothing more exquisitely beautiful than a bud of the common, or, perhaps, in a slight degree more lovely, the white Moss; and yet how often do we vainly look for it in some of the best Rose gardens?

One of the best ways of growing it that I remember to have met with was in the garden of that enthusiastic florist, the late Mr. Charles J. Perry, of West Bromwich, near Birmingham; he had a large bed of it, the plants in which were pegged down, and then from every eye a shoot started, and as they were planted tolerably close the bed in the flowering season was one mass of bloom. It is a very good plan where this idea is adopted, to plant some bulbs of *Gladiolus brenchleyensis* among them, and then, when the Rose bloom is over, and the dead leaves cut off, the bed will be gay with the brilliant flowers of the *Gladiolus*.

The Moss Rose is undoubtedly a "Provins" Rose; but how, where, or when it originated we have no record. But here is the true old Cabbage shooting forth in a new direction, but having, at any rate, one distinctive mark, its delicious perfume; but in the opinion of that wise old teacher, the late Mr. Rivers, it originated in Italy, and it would certainly be interesting to know how it came into existence. The French have been busy with this as with other classes of Roses, and especially in endeavouring to obtain perpetual or autumnal blooming Moss Roses; in this they have not been very successful. "Salet" bears this character, but it has not been extensively grown in this country—some of the most remarkable varieties seem to be like the common Moss, "sports" rather than seedlings.

In culture the Moss Rose presents but little difficulty, except in the case of Unique, which it is not easy to keep in good shape; some of the varieties are more robust than others, but all, with this exception, are amenable to culture. Like a good many things, they will endure hard treatment, but thrive best when their wants are well and properly attended to. In light soils they will thrive well on their own roots, and this is the most usual way of growing them; where they are grown in beds this is certainly the preferable plan, as there is no danger of large suckers springing up being mistaken for Moss Rose shoots, and thus usurping a place to which they have no right. Where the soil is stiff they do very well worked on either the seedling Brier or other dwarf stocks. With regard to pruning, there has been a difference of opinion, and sometimes very good authorities on each side have endeavoured to steer a middle course between hard and gentle pruning. This is a mistake; it should either be one or the other, and I believe that hard pruning is the better plan to adopt. Like other Roses they will be all the better for a good mulching in the autumn, to be taken off in spring, while the shorter portion of it may be forked in, the litter being removed.

There are many varieties of the Moss Rose, but we cannot do better in selecting than follow the lines of the National Rose Society, which in its catalogue of garden Roses has included nine Moss Roses. Three of these are the so-called Perpetual Moss, and therefore the number of Moss Roses of the ordinary type is six, although in this is not included the Crested Moss, as it is sometimes called, nor a new one which I believe ought to be more generally grown.

Baron de Wassenaar, raised by Victor Verdier, and sent out by him in 1854, is a vigorous grower, flowering in clusters.

Common or Old Moss.—This is too much known to need any description, and its origin is unknown, although supposed to have been introduced into England nearly three centuries ago.

Comtesse de Murinais, raised by Vibert in 1843, is a vigorous-growing white Moss Rose, very free, but not equal in beauty to our Unique.

Gloire de Meuseuses.—Raised by Vibert in 1852; rosy-blush colour; a large but not so elegant a flower as some of the others.

Lancé.—Raised by Laffay, and introduced in 1846; a large and very double Rose, rosy-crimson in colour, very bright, but it is not so dark as

Celine.—omitted, it is true, from the National Rose Society's catalogue, but certainly deserving of a place on account of its brilliant colour, although the flower is not quite full, but as all the Moss Roses are valuable only in bud, this is not of so much consequence.

White Bath.—This was found in a garden near Clifton, and sent out in 1810. It is very pretty, but I think not so much so as

Unique, which is often classed simply as a Provins Rose, but I do not see why the distinction should be made; they are all Provins Roses. This I think the most beautiful of all the white Moss Roses, the bud is more elegantly shaped and the moss longer, so as to give it a more graceful appearance. I know nothing more pretty than a bud of this, showing the white between the segments of the calyx.

Blanche Moreau.—This is a new introduction by Moreau, and is both vigorous in growth and free in blooming, and in these respects it certainly has the advantage over that previously named. It forms a very handsome well furnished bush, and all who admire this class ought certainly to grow it.

Crested Moss or Crested Provins.—This also is put amongst the Provins and not in the Mosses. It is very curious, more so indeed than elegant; but as a curiosity it is well worth growing.

Rose de Meaux.—A charming little Rose, a mossed variety of the beautiful Rose de Meaux, so sweet and double in itself, but if possible made more charming by the mossy addition. Said to have been found by Mr. Sweet in a garden near Taunton.

Little Gem.—This, an introduction of Messrs. W. Paul & Son, is an improvement on the preceding, being more beautifully mossed, and altogether a most delightful little Rose.

Crimson or Tinwell Moss or Damask Moss.—This is omitted in the National Rose Society's catalogue, but seems to be a very desirable Moss. It was raised at Tinwell, in Rutlandshire, and was so highly thought of that it was sent out at a guinea a plant.

I hope that this attempt to draw the attention of lovers of flowers to a beautiful but neglected tribe of Roses may not be without result. *Wild Rose.*

REPLANTING ROSES.

Some persons may ask, Why write about Roses in mid-winter? Their time is not yet! I must beg pardon of those who think or write in this strain, and beg to differ from them. It is because we are now busy replanting our beds of Roses, and planting out those that have been bought in, that it occurred to me to write about them. I was told the other day, by a man who thought he knew everything about gardening, that there was no need to trench the ground—he could not see any use in it. Probably there are many more wiseacres who can see no use in trenching; I will therefore explain that we trench the ground 18 inches or 2 feet deep, to allow the roots to grow freely into it, and we place a good layer of manure at the bottom of the trenches and half-way down, to supply the plants with nourishment during their season of root-activity. No fine Rose blooms can be obtained unless the ground be trenched and heavily manured. We are now replanting a bed of Tea Roses. I maintain that a Rose bed should be lifted and replanted every second or third year; and this for two reasons. The first and most important is that in some soils the quality of the flowers rapidly degenerates after the third year, even when the Rose beds have a good mulching of decayed manure annually. Probably because the roots work into an unsuitable subsoil. The second reason is that, whether the Roses are Teas, hybrid perpetuals, or others, the plants make an unequal growth. By this I mean that some varieties will make strong vigorous shoots while some will grow but little, and even in the minor struggle for existence in a bed of Roses the weaklings sometimes succumb to the strong. This may all be set right if the plants be taken up and replanted in the months of November or December, and in some bad soils it would be better for them if the replanting took place every second year, by this means increasing the number of the root feeders. A Rose bush which has stood more than three or four years without transplantation has few feeding roots, and these are at the distant main root extremities, the fibrous roots going further afield year by year, unless occasionally transplanted. I would like to add here that I am writing about the culture of Roses in the garden only, and not for exhibitors of Roses. Such growers will have to bud their Roses, and depend for the best blooms upon what are termed "cutbacks," that is, established plants of two years old. It may be added that exhibitors work on different lines altogether to the grower of merely garden Roses, and that the highest positions at the principal exhibitions can be reached only by long experience.

The soil of our garden is heavy and the subsoil wet, but it has been ameliorated by draining, and we have added to the depth of natural soil by raising the beds about 12 inches above the surrounding level. This is in addition to trenching the ground from the original level to the depth of 20 inches, the added foot of soil being made up with loam of good quality. Manure was dug in, and the sloping sides of the bed were made up with a turf edging, the grass being kept short by the shears.

The Roses do very well treated in this way, their vigour being remarkable. The ground is now being retrenched, and as the work proceeds the Roses are taken up and replanted. In doing this the workman must not injure the roots, and the Roses can be easily taken up without injury as the work of

trenching proceeds. The replanting affords an opportunity for removing root-suckers, which should be cut out with a knife close back to the point from whence they sprung, neglect of this precaution leading to the early appearance of fresh growths, and they will be even more numerous.

Damaged roots should be cut back to a sound part, and as the work of trenching proceeds so also should the work of re-planting. In case the latter cannot be done at the time, the plants ought to be laid in by the heels. When the replanting is finished the surface of the soil should be mulched with manures. I use the peat stable litter, which is also an excellent protector against frost and heat alike. In very severe frosts the Tea Roses are killed to the level of the manure, and if no manure or other protecting material were used, the Roses might be killed altogether. Where the dried fronds of native Fern can be obtained, it is excellent material to lay over the manure, or to use in its stead.

It is still, perhaps, a moot question as to which is the best stock for Roses. I find in our soil that nothing answers so well as the seedling Brier—it answering, if anything, better for Tea Roses than for hybrid perpetuals. Of course the Manetti is a good stock for Roses, and I have nothing to say against it. It is a good stock for light soils; and yet, notwithstanding the distinct looking leaves and growths, it may sometimes be seen, like the cuckoo in the hedge-sparrow's nest, in entire possession of the place, and the Roses conspicuous by their absence.

After the preparation of the ground, planting and mulching, the work is finished until pruning time—an operation depending upon the weather, for if frosts be severe in February and March it must be delayed until the weather has become mild. February, when the weather is kindly, is a good month in which to prune. After pruning is over, the first insect pest to attack the Roses must be looked for in the bud worm—being the earliest, and a very destructive one it is, getting into the young growths when they are an inch long, and eating the central substance out of them, and oft-times before it is observed. Be watchful early in the month of April, and with a needle make short work of them. The bud-worms destroyed, the Roses will grow freely as soon as mild weather sets in; but that mildness brings greenfly, a destroyer which increases with amazing rapidity. For their destruction aphid brushes are used, or syringing with tobacco or soft-soapy water. At last the flower will come to reward the gardener for all his patient care. Tea and hybrid perpetual Roses blooming in the autumn as well as in the summer, the plants need to be kept clear of mildew—a great plague to the Rose grower and always present, committing great damage unless destroyed by timely dusting with flowers of sulphur. Mildew and the Rose aphid together sometimes attack the young shoots at the late time of blooming, in which case sulphur thoroughly diffused in warm rain-water should be syringed over the plants. As to the best varieties to cultivate I have to say that the best varieties are cheap, because they are plentiful and well known. I am quite ready to admit that some good Roses are sent out every year, but there are a good many inferior ones. For my part I have most faith in English raised Roses, because the growers send them—at least sorts fitted for exhibition—to the exhibitions before they are sent out, and thus give the public an opportunity to see them before they purchase. *J. Douglas, Great Gearies.*

A CURIOUS DISCOVERY.—In the tartar of teeth from skeletons of the stone age, Mr. Charles White, of the Odontological Society of Great Britain, has found specimens of the food eaten by our prehistoric ancestors 3000 years or more ago. The fragments identified include portions of corn husks, spiral vessels from vegetables, starch husks, fruit cells, the point of a fish's tooth, and bits of wool, feathers and cartilage.

EXHIBITIONS OF CHRYSANTHEMUMS.

THESE are now so numerous that every town of importance has its show, and many places also of lesser pretensions. The flower-loving public appear to be attracted much more to autumn than they do to spring exhibitions, and it is probably owing to this fact that the Chrysanthemum is so generally popular. But there is after all a great deal of monotony about these constantly recurring exhibitions of what has been termed the queen of autumn flowers. One sees the very same style of group at all of them, varying only in size and in the quality of bloom found upon the plants; the trained specimens are also alike, and far too many of them presented in a flat and unnatural fashion. There are lines of stands of blooms of the most formal character, without a leaf to vary the parallelograms of cones of varying colour marshalled upon the painted green stands with such severe military precision; and there is now present in the mind of the observer the suspicion that the dresser-out has quite as much to do with the promiscuous given to this or that stand by the judges as the skill of the cultivator. Those who regard correct form as expressive of the truest lines of beauty see in these formal-looking incurved blooms the highest triumph of the florist's art. Others are conscious only of a tedious formality, repellent rather than attractive.

The great popularity enjoyed by the Chrysanthemum may be accepted as indicative that Chrysanthemum exhibitions will increase rather than diminish in number. With this certainty before us, is it unreasonable to require that, in order to prevent the obvious sameness seen more or less in all shows of this kind, and still more because this very feature is in danger of causing something like a revulsion in the public mind—is it, we say, too much to ask that novel features should be introduced to exhibitions? We have seen stands of blooms shown with 4 or 6 inches of stem and foliage, and this seems to indicate one direction in which a little agreeable change might be secured. The difficulty appears to be to ensure the flower-stems being in an erect and properly regulated position, so that the eye be not offended by an appearance of confusion and want of harmony. Bunches of pompon Chrysanthemums shown in this way have been seen at some exhibitions for a few years past, and have always commanded admiration.

At some important shows we have seen vases of Chrysanthemum blooms—some on a large scale for entrance halls and such places, and some on a smaller scale for table use, admirably arranged and shown in excellent taste. At a recent exhibition at Reading, although the vases were restricted to 5 inches in diameter, yet the space admitted of a large bunch of blooms being arranged in the most admirable manner. Epergnes and bouquets of Chrysanthemums should be encouraged also; the long-keeping qualities of the Chrysanthemum in a cut state fits it for room decoration at this season of the year.

The method generally adopted for showing the blooms of the fine and varied Japanese Chrysanthemums is one that seems to rob the blossoms of half their beauty. The fact that many of their blooms can be grown to a large size, from 9 to 15 inches in diameter, requires a stand of a different character to that usually employed to display Chrysanthemum flowers to the best advantage. They are not only too much crowded, but they are placed too low on the boards, which imparts to otherwise attractive blooms a flat and squat appearance. The main drawback to elevating the blossoms of the finely formed incurved varieties is, that the base of a flower will droop, and the symmetry is destroyed. The very opposite holds good in the case of the Japanese varieties. They gain in beauty when their basal florets can droop elegantly below the level of the involucre, and this also imparts an appearance of depth and solidity to the blossoms. What is wanted are stands in which the flowers can be placed wider

apart, and some method is necessary by which the blossoms can be also placed at a greater elevation.

These suggestions might appropriately enough engage the attention of the supporters of the National Chrysanthemum Society. Country societies are found looking to it as an executive qualified to legislate in the interest of this popular flower; and anything that can enhance its value, either as an exhibition or decorative agent, should be the concern of what we may regard as the leading organisation, whose main object it is to extend the usefulness of the Chrysanthemum. *R. D.*

ORCHID NOTES AND GLEANINGS.

OLDFIELD, BICKLEY.

THE *Phalænopsis* here—always an interesting feature—were many of them either in bloom, or showing forward spikes of bloom; *P. Stuartiana* had several blooms fully open, showing the brilliant red of the lip conspicuously. This is still a very scarce species. Of *P. grandiflora* were very fine pieces, and *P. Sanderiana* was beginning to disclose the colour in its buds of bloom. The foliage resembles that of *P. amabilis*, but is silvery-grey above, and the marbling like that found on *P. Schilleriana*. Many plants, healthy and dark green as to foliage, and the spikes large and long, were observed of *P. amabilis*. The plants of *P. Schilleriana* are going to flower well at a later date. This is a most beautiful species, and finds here a good cultivator in Mr. Heims. *P. speciosa* and many another were only just pushing up their spikes, and we were therefore not rewarded with a sight of their flowers.

Growing under apparently similar conditions to the *Phalænopsis* were plants of *Angraecum citratum*, with flower-spikes in a forward state, and the gorgeous *Vanda Sanderiana*.

In the house once used as an experimental-house, and where Orchids used to be hung up to the roof and exposed to full sunshine, we found a collection of *Odontoglossums*, and of those noted in flower, were *O. Alexandra*, *O. Pescatorei*, showing flower quite generally; *O. aspersum* (a supposed hybrid between *O. maculatum* and *O. Rossi*) was just indicating the colour in its buds, and *O. Harryanum* appeared to be progressing under the treatment afforded, the home-made pseudobulbs on the lately imported plants being every bit as good as those that were made in its distant habitat.

Of *Masdevallias* a few were ornamented sparsely with flowers, viz., *lilacina*, *ignea*, *Shuttleworthi*; the white with yellow tailed *Polysticta*, very small and curious; *Oethodes*, a pretty companion to the last-named—the flowers yellow; *Fraseri*, a Veitchian hybrid, and resembling *Veitchiana* in habit and bright colours; the showy *splendida*, also of Chelsonian origin, was showing colour. The *Cattleyas* promise for fine bloom, especially *C. Percivalliana*, which is to flower here for the first time this year; the *Trianae* section, *C. Warneri*, *C. Reueckiana*, *C. Mendelii superba*, *C. Backhousianam*. The *Oldfield Cattleyas* would not perhaps please those who prefer fine dark green immaculate foliage, and would be deemed unsightly; but of their flowering capabilities there can be but one opinion. The houses here are fully exposed the whole day, and get more sunlight, and as a consequence ventilation, than do others; hence the lighter colour and shortness of the leaves.

The *Cattleya*-house contains other species besides those: noticeable were good forms of *Odontoglossum Rossi*, many large pieces of *Cælogyne cristata* in variety, *C. Lemoinei*, *Angraecum eburneum* with several of its fine spikes of white and green flowers in fine order. *Vandas* and *Saccolabium giganteum*, the last-named a small plant bearing a raceme of pinkish-purple and white flowers. The spike is comparatively puny in point of size, but the foliage is larger than that of other *Saccolabiums*.

A goodly number of *Cypripediums* were observed in flower, and especially fine was the true *C. insigne* *Maulei*, a flower paler in colour than the type, and

perhaps always of a smaller size in all its parts: *C. i. albo marginata* is rather larger than *Maulei*, but is finely marked; *C. violaceum* and *C. Chantini*, varieties with handsome markings, were full of flowers. Several forms of *Lælia anceps* brightened the house with their showy spikes of flower; we remarked *L. a. Barkeri*, *L. a. Morada*, both with a lip of remarkable brilliancy and depth of colour: and *L. a. Hilliana*, the softer tints of whose flowers formed an excellent contrast to the other forms of *L. anceps*. The fine white *L. a. Stella* was found making good growth on a raft suspended near the roof. *Lycaste Skinneri* alba, a still uncommon variety, was bearing a few blooms. In all respects this collection of choice and rare Orchids keeps up its old reputation, and is well looked after by Mr. Heims.

THE SATYRIUMS.

These are very handsome when well grown, but our cool Orchid-house is too damp for them. If any one has a spare shelf near the glass in a light airy greenhouse, these and many other Cape plants would fill it better and give a better return for the care bestowed on them than most plants. I have flowered some very handsome *Satyriums*, and recently having seen a grand inflorescence of *S. carneum* at Mr. A. H. Smees's, at The Grange, Hackbridge, and knowing his skill, it occurred to me to ask him to describe his culture of these plants, and he says:—

"The *Satyrium carneum* has succeeded well, potted in rough fibrous peat and yellow loam in equal quantities, with a good sprinkling of coarse silver sand and well drained pots. They were grown in the open air from July till the middle of September, in a shady position. The greatest care is necessary in watering, as the thick fleshy leaves cover the surface of the pot, and if one gets slightly injured the whole leaf ultimately decays. Before the flower-spike appears the centre of the plant resembles *Hæmanthus coccineus* and is unfortunately a convenient place for water to lodge, which, if allowed to remain, very soon causes the plant to rot. When water is required, the best way is to immerse the pots in a pail of water and keep the plants under cover during rain. After the plants have bloomed they are gradually dried off, and when at rest the pots are stored in a dry airy part of the cool-house and require no further attention until they commence to grow again." *Harrow.*

DENDROBIUM TETRAOCTUM.

Like the majority of Australian *Dendrobes* this species is by no means of easy culture—a fact which perhaps accounts for its comparative rarity, notwithstanding the quaint and singular appearance of its flowers. Both in habit and in flower it is very different from any *Dendrobium* in cultivation. The pseudobulbs are four-angled, 6 to 10 inches in length, tapering towards the top and bottom. The sepals are about 2 inches in length, and produced into long tapering points; they are greenish-yellow in colour, with a few chocolate-coloured blotches; the petals are similar in shape, but shorter, and without blotches; the lip is creamy-white, marked with bars of pale rose. Minus the two petals, the general aspect of the flower would not be unlike that of a *Chimæroid Masdevallia*. It is figured in the *Botanical Magazine*, t. 5256, but apparently from a poor variety: a better and more distinctly marked form is now in flower at Kew. The plant requires stove treatment, and should occupy the lightest position in the house. *W. B.*

SOBRALIA SESSILIS.

This species, which in habit is one of the dwarfest of the genus, was introduced from British Guiana about 1840, but it has not at any time been common in cultivation, and exists at the present time in only few collections. Its flowers, like those of *S. macrantha*, are individually rather fugacious, but while they last they are extremely chaste and pretty. The sepals and petals are white, faintly tinged with rose, ovate in shape, and form a full open flower 2 inches across. The lip is of a pale purplish colour, suffused with yellow; the sides turn up and meet over the column. The flowers are produced from the top of slender stems 1—2 feet high, which con-

tinue sending up flowers singly for several months. A plant in the warm Orchid-house at Kew has now been flowering at irregular intervals since early summer. According to accounts published at the time of its introduction, it is found growing in hot, dry situations. If this be correct, it shows the advantages which are sometimes the result of departing from natural conditions; for the plant mentioned above, which is in vigorous health, is kept very moist throughout the year. As the roots mostly develop in a horizontal direction, a rather shallow pan is best to grow it in. *W. B., Royal Gardens, Kew.*

BRASSAYOLA CUCULLATA VAR. CUSPIDATA.

A species as beautiful in its flowers as it is curious. The leaves are pendent, green, but quill-like, with a sharp point at the extremity. The white star-like flowers are at the end of long slender stalks, each is about 5 inches in the long diameter, with narrow, lanceolate, acuminate, spreading segments, and a lip of similar form but lacinate at the edges near the base, and hollowed out in front of the short white column. *Lindenia*, t. III.

AGANISIA CYANEA.

A Brazilian species, with creeping rhizome, fusiform pseudobulbs, lanceolate leaves, tapering at the base into a short stalk, and basal, many-flowered racemes. Each flower measures about 2 inches in its largest diameter, is of oblong outline, with obovate spatulate segments of a bluish colour, a lip narrow at the base, dilated into a trowel-shaped rosy-lilac lip, with stripes of a deeper tint. The column is white, with two rosy-lilac wings. This plant, which is very rare in cultivation, flowered last autumn in the Orchid-houses of the "Horticulture Internationale." It requires a damp warm atmosphere during the growing period, and to be shaded from the direct rays of the sun. *Lindenia*.

IONOPSIS PANICULATA VAR. MAXIMA.

An elegant Brazilian species, with lanceolate leaves and long slender flower-stalks, bearing a many-flowered panicle of moth-like flowers, the segments of which are small as compared to the large ($1\frac{1}{2}$ inch in diameter) roundish notched lip, which is white, with a lilac blotch at the base. *Lindenia*, t. III.

DURANTA PLUMIERI.

How many people nowadays grow this old-fashioned shrub we cannot say, but certainly it has become scarce out of botanic gardens, though its pretty blue flowers, borne in great profusion towards the end of the branches, as Mr. Nicholson describes them in the *Dictionary of Gardening*, render it a suitable plant for the decoration of the stove in autumn. The *Durantas* are very variable—some spiny, others destitute of thorns; some with serrate, others with entire leaves. The variety we are now enabled to figure (fig. 9), owing to the kindness of Mr. Woodrow, has white flowers, and is a great favourite in Indian gardens, not only for its flowers but for its amber-coloured fruit, which is said to remain on the plant for many weeks. The manner in which the calyx-lobes become twisted as the fruit ripens is noteworthy. The species is widely diffused throughout tropical America.

THE CROTON.

Few plants rival *Crotons* for beauty and gracefulness of foliage, and although few plants are less neglected by gardeners, careful attention is necessary if success is to be attained in their culture. As regards their propagation, they can be struck from cuttings at almost any time of the year, the spring being, however, the best time. Healthy, well-coloured points of shoots should be selected for the purpose, and inserted in small pots, with a thick layer of silver-sand on the surface of the soil; the pots should be well drained, and almost any kind of light soil will do until the cuttings have struck root.

A propagating case, or a hand-light with a movable top, is a very good help in striking Crotons; or a bell-glass; failing these aids, potting off should be done as soon as sufficient roots are formed. As the Croton is much employed for table decoration, any that are set apart for the use of pots will not need any larger size than 2½'s, height and size of plant being governed by requirements. If large specimens are sought for, potting must be strictly attended to, so as to keep the plants growing freely, for if the growth be checked by the plants becoming too much pot-bound, the specimens will be deficient in leaf-

watered regularly, and the water should be at about the same temperature as that of the house. When sufficient roots are formed in the new soil, manure-water may be given in a weak state occasionally until the plant becomes rather pot-bound, when it can be given at greater strength. The drainings from a manure-heap is the best if they can be obtained, and if not, I would strongly recommend Thomson's Vine and Plant Manure to be mixed among the soil used for potting them. Syringing the plants is an operation which, if performed properly, will prevent insects from infesting the plants so as to cause any trouble.

may range from 75° by night to 80° and 90° by day with sun-heat.

All pinching and cutting out of points is best done in the autumn or winter months, and the plants should be tied in of the required shape, which may be either bush or pyramid; the point must be taken well back so as to get a good break of three to four buds below, and the desired shape should be determined on early, and then, if large plants are wanted, a splendid one can be grown from a cutting in about four years.

Thrips, which are partial to the plant, can be destroyed by fumigating, and for white thrips tobacco-water is by far the best insecticide. This variety generally attacks the young leaves, causing them to fall off, and especially is it partial to Croton Hawkeri; but if pure water (soft) be forcibly applied with the syringe, few insects will be found to harbour on the plants, and sponging of the leaves should be done occasionally.

As regards the best varieties to grow, the following may be taken as representing the best:—Warreni, Chelsoni, interruptus aureus, Johannis, Queen Victoria, angustifolius, Weinmanni, superbus, Earl of Derby, and Disraeli—the latter having three-lobed leaves. *May flower.*

FIG. 9.—DURANTA PLUMIERI, VAR. ALBA. (SEE P. 11.)

growth. The early autumn is the best time to pot them, as by so doing the roots get a firm hold of the fresh soil by the springtime.

The best potting material is turfy loam with the fine soil sifted out of it, and a liberal mixture of sand. Artificial manure may be used with advantage, but splendid plants can be grown without any at all. The pots used must be thoroughly clean, and well drained with large pieces of potsherds; no small sherds should be used, a surer and better drainage being thus secured. Watering is of much importance, and on the judicious administration of it depends success.

Crotons are moisture-loving plants, and must be

If scale is troublesome, they must be picked off with a small pointed stick, and the plants afterwards syringed with petroleum at the rate of a wineglassful to four gallons of rather hot water, and kept regularly stirred about while using it. In the summer months forcible syringing must be done every evening, and plenty of atmospheric moisture maintained in the house, which should be closed early to allow the temperature to run up from 85° to 95°, all steaming troughs being kept filled with water, and at times with liquid manure, the plants being kept growing. The most suitable temperature in winter is 65° at night, to 75° by day with sun-heat; the summer temperature

TRADE NOTICES.

MESSRS. HURST AND SON.

AMONGST the many notable firms which have risen into importance during the last fifty years and which owe their present flourishing condition to the energy and intelligence of the directing mind, the firm of Hurst & Son., of 152 and 153, Houndsditch, London, holds a foremost place. But little is betrayed by outward sign of the amount of business that is transacted within their precincts. Standing before the rather old-fashioned premises, which comprise three wholesale shops, and offices, and roomy warehouses in the rear, there is nothing about its external aspect differing from that of many other similar places in the city of London. A surprise is, however, in store for any one visiting the cleaning, packing, order departments, and warehouses at the rear. The storage space, large as it is, does not contain all the produce, but portions of each, for prompt despatch, the remainder of the bulks being at railway stations, and warehouses in London and other places. This perforce must be so with goods of such large bulk as Beans, Peas, grass seeds, and Mangels, the mere cartage transport of which from the points of arrival, and the costliness of warehouse space in the City, being items of cost which must be taken into consideration at any time, and of extreme importance in these days of keen competition. The tour of inspection lately undertaken by the writer was commenced at the Houndsditch entrance; the first place being a long room, whose windows looked out on Houndsditch at one end, and into the large yard at the rear. Here the wholesale vegetable seeds are put into bags, or packets, ready for requirements, and later for removal to the final packing up, which takes place elsewhere. Here were noticed great bins filled with varieties of Carrots, Spinach, Onions, Beets, Cabbages, Kales, Savoys, Broccoli, &c.

With regard to the quarters whence these seeds come, we were informed that the Turnips and Swedes are chiefly of Bedfordshire and Kentish growth; Cabbage and Broccoli seed is chiefly grown in Essex, and Onion seed comes from the headquarters of Onion culture—Bedfordshire.

In a room off the side were a number of women and girls busy in making up various sized packets in readiness for future orders—a clean feminine employment, not involving either hard labour or grimy persons or clothes. Stepping out-of-doors we entered a building at one end of which is the despatch office, whence no single item sent to customers is allowed to depart till after careful scrutiny. This office contains samples of goods lying at senports, railway stations, canal-wharves, and similar places of storage. Frequently sales are effected from

these samples only, the goods never coming to the warehouse in Houndsditch at all.

In the neighbourhood of this happy dispatch office were stacked hundreds of bushels of Beans. There were Beans Broad, Beans French, Beans of Butter (Butter Bohnen)—capital eating these last, but not making much way in our country, because English housewives imagine that the pods of "good" Beans should be green, which these are not, but yellow, like butter.

The warehouse we are now in is on the Church Row side of the range of buildings, into which it has an entrance, and an Otto gas engine working silently affords the means of loading and unloading heavy goods. The warehouse is devoted to the storage of Peas. On all the floors sacks are piled ten sacks high, excepting narrow passages, which bewilder the explorer in the uncertain half light, which run through and around these piles of Peas. Women were sorting Peas at tables running along in front of a row of large windows, other women were sifting out, in small machines consisting of a series of sieves, Peas that were faulty in samples before passing the seed to the women at the table. The sorting done by the latter, consisted of picking out weevil-eaten seeds, and such other inferior or small seeds as the indiscriminating sieve machine had let pass through its meshes. So much Peas is getting monotonous and we long to escape up the steep ladder-like stairs only to find that the Peas have ascended before us, and that the room is as full as the one we have left below. One cannot but be impressed by the immensity of Pea matter on all sides, the produce of 1500—2000 acres of land. These enormous quantities of Peas are grown by farmers and others, who enter into a contract to grow a certain quantity at a price per quarter of 8 bushels; and be the nature of the season what it may, and the yield ever so small, the contract holds good. In a favourable season the early Peas are delivered at the warehouse during August, and the later varieties in succession as harvested. Certain kinds of Peas are in large demand—such are Daniel O'Rourke, Early Prolific, Advancer, Prizetaker, Champion of England, Laxton's Supreme, Ne Plus Ultra, Veitch's Perfection, and British Queen.

It was with a feeling of relief that we again ascended to a floor piled with sacks to the joists as before, not with Peas, but with seeds of Cauliflower, Cabbage, Broccoli, and Onion, in numerous varieties, and the seeds of 1887 growth. Another floor above this one was heavily laden with seeds in sacks, overpiled, of Radishes, long and short, Spinaches, Sweet Peas, and Mignonette.

Fancy, ye retailers and sowers of pinches of Mignonette seed, what labour and cost the 5000 lb. of seed of this perfumed favourite mean in saving and cleaning the same! How many acres of the plant must be grown ere the weight of 2½ tons is obtained, and how much labour was spent in getting it ready for you!

Seed of Mignonette and many other kinds of annual flowering plants come from the county of Essex, although other parts of England and the continent of Europe supply considerable quantities. Of Sweet Peas, in mixed colours, as much as 200 bushels were in stock, and in separate colours about 100 bushels. Another floor near the top of this warehouse, measuring 20 yards in length by 16 yards in width, contained sacks of seed of Parsnip and Carrots; and at the very top were Carrot and Beet seed in bulk; this floor was made practically air-tight, the better to preserve the vitality of the seed deposited therein.

In the busy season of cleaning and despatching seeds, about 150 to 200 women, besides men and boys, are employed in this single warehouse, at rates of wages that vary with the individual's dexterity.

The warehouse for Turnip and Swede seeds is apart from the others, and has a distinct staff of men who execute all orders for these seeds. Screening and sifting the seeds is carried on here by means of cleverly designed machines of the firm's invention. A floor in this warehouse would measure about 12 yards by 18 yards, and the stocks stored at this season are very large, sacks being piled from floor to

ceiling, 8000 sacks being about the quantity then in store. The cleaning is done by means of screens and sieves, the seed falling in some instances from floor to floor, until it appears at last perfectly free from light and weed seeds.

Besides the premises in Houndsditch is another large warehouse in Butler Street, not far from the Jewish quarter of Aldgate. The area on which it stands is about 30 yards by 30 yards, giving floor-space equal to 1 acre. Here were stored hundreds of tons of Clovers—white, red, Alsike, Lucerne, and Cow-grass, predominating.

Natural grasses find a place on some of the floors, and much of the seed was still in the sacks in which it was imported. Here were observed a large bulk of Foxtail-grass from Finland in unwieldy bags of roughly woven material, and feeling like nothing so much as a feather-bed. Cocksfoot and Rye-grass from France, and Dogstail grass from Holland, occupied a large amount of the space on different floors. The mixing of the various natural grasses, for the varied purposes to which they are put in field and garden, is done in this building. Of Timothy and red Clover, and Meadow Fescue and Cocksfoot, very large quantities come from the United States of America and Canada; and we observed English, Scotch, and Irish perennial Rye-grass in enormous bulk.

Natural grasses and Clover are the products of many different parts of Europe and North America, and beside the country before-mentioned, Sweden furnishes Timothy and Alsike, Austria and Germany supply Alsike, white and red Clover, Lucerne; Sainfoin and Italian Rye-grass come from France.

Some varieties of Mangel Wurzel seed were stored here, the quantity of which was very large. Much of the Mangel Wurzel seed is the growth of Kent, Essex, and Cambridgeshire. Where do these enormous stocks of seeds go to? The agricultural seeds, especially those of grasses and Clovers, are largely shipped to Australia, New Zealand, California, Canada, and the United States of America, the two former countries taking seeds of suitable grasses to lay down immense tracts of cleared scrub for pasturage purpose: in one instance 100,000 acres were so treated with excellent results. Smaller but increasing consignments of agricultural seeds are made to the Cape and Natal. And not only are mixtures of grasses extensively used for laying down new pasture land, but the preparation of seeds for the improvement of old pastures is an important matter also, and is especially considered by Messrs. Hurst & Son.

The United States is a good customer for flower and vegetable seeds, and considerable quantities are exported to India, China, and Japan—in fact, to whatever habitable part of the globe our wandering race have migrated. Seeds which have to be sent to distant parts of the world, and have therefore to pass through different degrees of temperature are found to travel in the best condition when packed in air-tight tanks. To meet this requirement the firm pack seeds loosely in canvas bags, which are then put into the tanks through the manhole, and being loose it is found possible to pack into the tank a larger quantity of seed, than could be done with firmly made-up packages. When quite full the covering of the manhole is fixed securely, and all in proper condition to withstand the—for seeds—trying journey.

Quite recently an additional space has been secured for the flower seed department by the acquirement of No. 151, Houndsditch. Here is brought together the pictorial seed-packet and German seed-packet business—a branch which is yearly increasing in volume. The flower seeds in bulk and in packets occupy about 1000 drawers in this portion of the premises.

In an establishment of this magnitude a much longer time than that occupied by the writer of this note would be required before an exhaustive inspection could be made, but enough will have been noted to give the reader some insight into the extent and variety of business and the care taken in its management by a large firm like this.

THE ORANGERY.

ORANGE TREES IN POTS.

I WAS pleased to read an account of the successful culture of Orange trees in pots at p. 755 (vol. ii., 3rd ser.) I have for many years advocated the culture of these in pots, and more than once detailed the system of culture I have found best in practice. This is now the season for reaping the fruits of twelve months' labour.

During the months of November, December, and January the Maltese Blood and the St. Michael's varieties continue to produce well-developed, well ripened fruit bursting with juice, indeed there is always a difficulty to prevent the skins bursting with the juice. The best way to prevent this is to keep them short of water at the roots, with a rather dry atmosphere at the same time. This is quite necessary when the fruit is ripe; and at that time there is no great danger of the skin cracking: it is when the fruit is approaching the ripening stage that the danger exists, and that precautions should be taken. The little Tangierine variety is the more useful because it produces its delicious fruit in September, and the fruit is scarcely gathered before the blossoms appear for next season's crop. The trees ought to be kept rather cool for a short period, and advantage may be taken of this time of rest to repot any of the trees that require repotting; but this is not required except about once in two years; and the season in which they are not repotted a good surface dressing is desirable. Before applying the surface dressing, a portion of the top soil ought to be removed, but not to the extent of disturbing the roots very much. I remove all the soil down to the point where the fibrous roots are numerous, and pick it out from amongst them to a very limited extent, with the tine of a steel digging fork—one may be broken from a worn out-fork. An appliance of this kind can be laid aside, and is useful for removing the surface soil from any class of pot plants for top-dressing, and also for disentangling the roots before proceeding to repot any of the trees. In this place it is also well to remark that if a fruit tree, or any tree, has to remain in a pot for, say, two or three years, it ought to be placed in it carefully. Let the pots be clean at least inside, and quite dry. If they are new, let them be soaked for a few hours in clean water, and dried before using. Place clean potsherds over the hole in the bottom, in such a position that the water may drain down equally well in every part. Spread over them a layer of fibrous turf from which the clay particles have been shaken out. The compost ought to be ready mixed six weeks or more before using it, and not too dry. The black peaty soil in which Orange trees are potted and sent to this country from the Continent will not do at all for trees intended to produce fruit far superior to the best imported. Good fibrous loam—the tougher the fibre the better, and not too much decayed—is best. Let it be torn up by hand, and mixed with a fifth or sixth part of stable manure; some crushed bones and charcoal broken up into pieces from the size of a hazel-nut to a walnut, an inch or so of the potting compound, may be spread over the fibre, and pressed in firmly; the tree which has been prepared for potting, should have its base resting on this, with the upper part an inch or so below the rim; and a space all round the ball of roots, of 1 inch to 2 inches; fill in all round with the soil, beating it down rather firmly with a wooden rammer. When the trees are treated in this way, they grow with great vigour, and speedily fill the new soil with roots; but in the early stages of their forming roots, care must be taken not to give too much water, as an excess of moisture in the fresh rich soil would cause it to become sour. Orange trees and Pine plants succeed well together, if the trees can be placed in a part not occupied by the Pines. I find they will do no good under the shade of Vines, or in fact anything else; even the necessary light shading required for a hothouse containing plants is inimical to their perfect development: this I have found out in practice. I tried to grow them in a house where Cattleyas did well, but found the fruit was inferior in flavour, and none of it cracked in any way. I therefore advocate free exposure to sunlight, and a high temperature; indeed, during the summer months, the temperature would rise to 90° and 100° in the afternoon, with the sun shining directly on the leaves; but this is what they delight in, and must be very much like the climate where Oranges ripen best; of course, at the time of shutting up the house, the trees are freely syringed with tepid

water, and the moisture arising in the house speedily condenses on the glass, forming a film which, to a certain extent, must intercept the sun's rays. *Jas. Douglas.*

Orange Trees.—At this season, Orange trees grown to supply ripe edible fruit will be in a house whose temperature will range from 55° at night to 65° and 70° by day—the higher point being reached by sun heat and not by firing. With Oranges used to embellish the conservatory, the course to be pursued consists in maintaining the house at a day warmth of 55°–60°, and during the night at 45° or even less.

Watering the Orange trees in tubs in the cool house is a matter requiring much judgment, and should not be deputed to young or inexperienced men, over-watering being especially detrimental to the health of the trees.

If ample drainage be afforded to trees in tubs, once a month will be sufficiently often to give water to plants in tubs of 2½ feet to 3 feet in diameter; smaller sized tubs and pots requiring water perhaps at rather shorter intervals. During the winter months, when bad weather often compels work to be found for the gardeners indoors, the opportunity should be seized to have the plants cleaned of black mould which affects the older foliage; and of white scale and dust. All of these in crust either the foliage or the wood, and are harmful in various degrees to the well-being of the trees.

For scale and blackfungus, petroleum emulsion is excellent; sponging the leaves with a sponge, and scrubbing the bark with a brush.

Aged trees frequently set too large crops of fruit, and if all the fruits are allowed to remain on the tree its energies become proportionately weakened—short growth, small foliage, and a tendency to become affected with the above-mentioned insect, and accretions. It is, therefore, in cases of excessive fruiting necessary to reduce the number of the fruits, as is done with other fruit trees under cultivation. The fruits left will be finer, and therefore more ornamental, and although they will hang on the trees long after they are ripe, the greater portion should be gathered before the opening of the blossoms in the spring.

Fresh tubbing or potting need not engage attention before the end of March. *M. F.*

THE FLOWER GARDEN.

HERBACEOUS BORDERS.—There is an increasing demand for hardy perennial plants, and every probability of its enduring for some considerable time. Although the time for making and arranging beds and borders is now some five or six weeks late it is not yet too late to proceed with the work, providing it be taken in hand in mild weather and completed forthwith, and to be rewarded with a fairly good display during the summer and autumn months, and as doubtless there are some amongst our readers who from various causes were unable to take advantage of the proper season, and are still desirous of not losing a year, we give a few details regarding the arrangement and selection of a fairly representative collection of sufficient variety. In the making of new borders, and where the choice of a piece of ground is free, preference should be given for an open situation and a well-drained soil; but this is not an absolute necessity, as many perennial plants will grow fairly well almost anywhere; however, it is as well to bear in mind that there are places which may be described as bad, the worst being in the immediate vicinity of large trees, whose roots impoverish the borders, and the branches in the summer months unduly shade the plants growing near. There is no objection to having a border in front of dwarf growing shrubs with trees in the background—indeed this is where we most frequently find one in private gardens, neither is there any thing objectionable in their being in close proximity to a fence or a wall having an aspect facing east, west, or south. Having selected and marked out the extent of the intended border, the ground should be trenched, and if out of condition a dressing of decayed manure should be worked in as the digging proceeds. If the soil is of a clayey nature and liable to “bake” on the surface in hot weather, nothing is better than mixing a liberal addition of burnt clay, wood ashes, leaf-mould, and finely-sifted cinder-ash with the staple. The labour involved in this extra work will be compensated for afterwards by the finer growth of the

plants. In planting an open border—let us say 13 feet wide and of any length—the arrangement of plants should be of such a character that the border will present a double face, the tallest plants being put in the centre, and gradually reducing in height down to the outside. For a border of this width seven rows of plants will be ample, and may be arranged as follows:—Central row, Delphiniums of sorts; along with these may be Pyrethrum uliginosum and Helianthus. The above will average in height from 4½ to 6 feet. The second row should be at a distance of 2 feet from the preceding, and may consist of *Solidago canadense*, *Spiræa arvensis*, *Michaelmas Daisies* of sorts, then *Bocconia japonica*, *Oenothera grandiflora*, *Papaver bracteatum*, *Verbascum nigrum*, *V. niveum*, and *Lilium candidum*. The majority of these will range from 3 to 4 feet. The third row from the centre should be at a distance of 18 inches from the second, suitable plants being *Asphodelus luteus*, *Anemone japonica*, *Achillea ptarmica fl.-plena*, *Aquilegia coerulea*, *A. chrysantha*, *Aster dumosus*, *A. amellus*, *A. grandiflorus*, *A. bes-arahiens*, *Astrantia major*, *Chrysanthemum arcticum*, *Dielytra spectabilis*, *Dictamnus fraxinella*, *Doronicum caucasicum*, *Geum coccineum*, *Hemerocallis flava*, *Iris amœna*, *I. Kœmpferi* and its varieties, *Lobelia fulgens*, *L. siphilitica* and varieties, *Lychnis chalcœdonica*, *Oenothera Fraseri*, *Phlox*, florists' varieties: *Rudbeckia Newmaniana* and *Stenactis speciosa*. The next row should be 8 inches from the edge of the borders, and may be planted with *Campanula carpatica*, *C. collina*, *Draacocephalum austriacum*, *Gentiana verna*, *Hepatica triloba* and its varieties, *Iberis gibraltarica*, *Tussilago farfara variegata*, *T. fragrans*, *Veronica candida*, *V. reptans*, *Violas* of sorts, *Helleborus niger* and varieties. Instead of scattering herbaceous plants indiscriminately through the border, an attempt should be made to group colonies of plants of one variety, or of one species together; this will add much to the interest felt by the observer, as the same thing, when once seen, will not be met with again in another spot. Before planting has commenced tread the surface of the border down firmly, and as the planting proceeds press down each plant also, and finish off with a top-dressing of decayed manure. In the event of dry weather being experienced at a later period occasional waterings will be necessary and beneficial till the roots have taken a firm hold of the soil. Avoid at all times the common practice of forking over the surface-soil merely for the sake of giving a neat and clean appearance, for on borders planted with subjects of this character, the only garden tools that should be used afterwards are a Dutch hoe, rake, and trowel. *J. Horsfield, Heytesbury.*

PLANTS UNDER GLASS.

THE CONSERVATORY.—This structure in many cases is attached to the mansion, and the general effect externally, or from an architectural point of view, frequently gets more consideration at the time of erection than do the arrangements for the well-being of the future occupants. Now that the Chrysanthemums are nearly over, Salvias will be found useful, although it is true they are not so useful for cutting as purposes, for intermixing with other plants. Owing to their varied and distinct colours some are very attractive subjects. Amongst the best for conservatory decoration are *S. Bethellii*, with its rosy-crimson flowers and bright-coloured bracts; *S. ianthina*—this is a lovely species, having large deep violet-purple flowers; *S. splendens*, and *S. Brunatii*, both of a vivid scarlet. These are now just at their best, and will soon be over, to be succeeded by *S. celestina*, a free-flowering sort of a beautiful shade of blue, telling well amongst other plants; *S. rutilans*—this is one of the best, with its glowing red racemes of flowers—*S. Camertonii*, purple-brown flowers; *S. Steerii*, a strong-growing scarlet; *S. Gondotii*—this species has a dwarf bushy habit, and yields a profusion of its light many flowers for a long time; *S. elegans* and *S. gesneriflora* var. *splendens* are two of the best; *elegans* has a free branching drooping habit, forming a perfect pyramid of flowers, and is a good plant to stand in isolated positions.

To have Salvias in good condition for winter-flowering it is best to raise a fresh batch of plants annually, and the present is a good time to put in cuttings. Select the points of strong healthy shoots, insert them in threes round the sides of small 60's,

using rather sandy loam. Stand them where they can have a rather close moist atmosphere—about 55°—they will root in about three weeks, and may then be potted on singly in 60's; return them to their former quarters until they begin to grow, afterwards hardening them off, and placing them with the Chrysanthemum cuttings, which will now be in process of being potted off.

The Forcing-house.—Continue to introduce fresh batches of plants from the reserve stores. It is always well to err on the safe side by bringing in a few more than you think will actually be required, and should you be fortunate enough to get all your batch to turn out well—a few extra flowers never come amiss. Lily of the Valley will now be coming in freely—do not be in too great a haste to remove the plunging material. If it is uncovered too soon, it is very difficult to get the flowers to open properly afterwards. After the flower-spikes are well up and are showing colour, remove the plants to a cooler house, the foliage will then develop, and this if the pots are to be used for decorative purposes, makes them look much better. Deutzias are now coming on rapidly, if they are weakly they may be very much improved, while their racemes are developing, by the application of liquid manure. *Astilbe japonica* (*Spiræa*) is also much improved by this kind of treatment; if the ordinary sources of liquid manure are not available, an ounce of nitrate of soda to the gallon of water will answer—it gives that kind of luxuriance and dark green colour to the foliage which is so much admired. Examine Tulips, Daffodils, Polyanthus Narcissus, and Hyacinths. The latter may be pushed on rather faster than the others, as they are likely to have more roots; unless there are plenty of roots, hard forcing will only end in abortive flowers. This is especially the case with Tulips. If not already done, lose no time in getting in some Ten Roses, and for the earliest batch we prefer plants that do not require potting, merely removing the loose surface soil from the pots, and putting on a little quantity of any of the concentrated fertilisers, re-surfacing with fresh soil. If it can be managed they are better if started in a temperature of about 50°, until they have broken away. Unless it be urgent, do not keep up an extra high night temperature in the forcing house, say a minimum of 60°—rather allow a considerable rise during the day. *F. Ross, Pendell Court.*

THE HARDY FRUIT GARDEN.

PLANTING.—Where this has been delayed, the change to milder weather will enable it to be proceeded with. Having selected the sites to be planted, proceed to dig the holes, which for standard trees should not be less than 3 feet in diameter, 2 feet in depth, the soil at the bottom of the hole being well broken up. In planting the trees throw in some good sound loam, chopped up with a little well rotted manure added, and for Cherry trees add lime rubble. This may appear unnecessary to many, but fruit trees that have this extra labour expended upon them at the time of planting always grow better and fruit sooner than those planted in the ordinary soil.

Should the holes be wet, drains must be made in connection with the nearest drain to dry the ground. Let the mouth of the drain (which in the neighbourhood of tree roots is best made with rubble) project just inside the hole, then put in a good layer of brick rubbish or any suitable material that may be at hand, and on this place some whole turves, the grass side downwards. After the trees are planted they should be staked and tied loosely to the stake, to prevent wind waving. To prevent the cutting of the bark use haybands or strawbands for ties provisionally, the final fastening being done when the soil has settled. Pyramids and bushes may be planted 8 feet apart, and kept summer pinched, and standards should stand 21 feet apart each way.

For growing as cordons, upright or oblique, and planted 2 feet 6 inches apart, the following Pears are good varieties for the purpose:—Clapp's Favourite, Brockworth Park, Beurré Giffard, Duchesse d'Orleans, Winter Nellis, Marie Louise, Marie Louise d'Uccle, Beurré Hardy, General Todtleben, Maréchal de la Cour, Ouyenné du Comice, Beurré Superfin, Chamonitel, Olivier de Serres, Bergamot d'Espéren. There are a great many more varieties that would succeed as cordons, but the above will be found to bear fine fruit of first-rate flavour. *A. Ward, Stoke Edith Gardens, Hereford.*

Advertisers are specially requested to note, that, under no circumstances whatever, can any particular position in the paper be guaranteed for advertisements occupying less space than an entire column.

		{ Miscellaneous Plants and Bulbs, at Protheroe & Morris' Rooms.

The Royal Horticultural Society.

AMID dismal surroundings the first meeting of the year was held on Tuesday last. The conservatory was rendered gay with Primulas from Messrs. CANNELL, Cyclamens from Messrs. H. PAGE & SON. Mr. TAUTZ contributed some Cypripediums, which attracted much attention; Mr. F. SANDER showed an Angrecum, while from Sir GEORGE MACLEAY's garden Mr. ROSS sent some spikes of the lovely Oxera pulchella, a white-flowered Clerodendron-like shrub, of first-rate quality as a decorative plant, and of which we hope to be able shortly to give an illustration. At the Fruit Committee Mr. RIVERS showed how a Quickset hedge may be made to yield bushels of fine Medlars. Mr. ROBERTS, of Charleville, showed bunches of his White Gros Colmar Grape, which had good looks, but which did not find much favour from the experts. The Scientific Committee was very well attended, and numerous interesting communications were made to it, of which we shall give a record in due season; but, after all, the most noteworthy feature was the large attendance of zealous committeemen, and this we look upon as the most hopeful of the signs of the times.

A society which, even in its period of depression, can secure such an attendance of men eminent in their several departments is in anything but a hopeless condition. The wonder is that, given such a splendid army—of which, as it is quite evident, the Society can command the willing service—no organising leader comes to the front to avail himself of such excellent material. We have heard it whispered that the

Society is getting too botanical, but if that really be so whose fault is it? Surely if one section of the community shows some signs of energy, is that not an additional reason why the others should do so too?

Apart from the ordinary business of the three committees the chief interest centred in the proceedings of the special meeting. This was summoned in order to confirm and render legal the proceedings at the preceding meeting, when, as it will be remembered, an outside committee was appointed, or perhaps we had better say re-appointed, to confer with the Council, and offer suggestions upon various matters, such as the necessity or otherwise of obtaining a new charter (the old one being by force of circumstances and effluxion of time obsolete as to a large number of its enactments), the construction of new bye-laws, the appointment of new members of Council, and other matters.

At the special meeting, presided over by Baron SCHROEDER, Dr. HOGG read the minutes of the last meeting, which were duly confirmed and legalised. Mr. BARN and Mr. HERBST took the opportunity of urging the necessity of establishing a new grade of Fellows, paying a lower rate of subscription, and who should be entitled, in their degree, to a share in the government of the Society. Representation should, in the opinion of the speakers, follow upon taxation—a sentiment in which we heartily concur. The outside committee, now duly legitimatised, set to work immediately afterwards, but it would not be right to chronicle fully their proceedings, which for the time are to be considered in the same light as “unread proofs,” which have not been revised, and have not received the author's sanction as to publication. We shall not, however, violate any confidence when we say that the first step of the new Committee was to add to their numbers so as to secure the representation of various interests, such as those of practical gardeners, representatives of the special societies, like the Rose and the Chrysanthemum, and local horticultural magnates. All these matters were formally taken into consideration, and we believe many gentlemen, selected on these principles, will be asked to join the committee. One difficulty at starting will be found in the circumstance that many of the most suitable men are not fellows of the Society, nor likely to be, so as long as there is no guinea or half-guinea subscription, and so long as the special societies drain away so much that should serve to enrich the old Society. The President, Sir TREVON LAWRENCE, also asked for suggestions as to the nomination of new members of Council, and this business was proceeded with on the same lines as those regulating the formation of the Committee. It would not be proper to discuss these details in their present inchoate stage, but we do most earnestly beg the Council to pay heed to the earnest desire of practical horticulturists for fuller and more satisfactory representation on the Council. There is a feeling abroad that the botanical element is likely to be too prominent, and while recognising the exceeding value of this section, we nevertheless fully concur in the principle that the practical element, including the commercial section, and more especially the practical gardeners, should be even more fully represented in a horticultural society. At the annual meeting in February, the Fellows at large will have an opportunity of making their wishes on this point heard, and we heartily hope they will not neglect their opportunity, and not tacitly assent to any proposal either of Committee or Council till they are assured

of its propriety. If they do remain silent and sequacious they must not hereafter complain that their interests have been neglected.

The question of site for the reorganised Society has not yet been resolved; it is more than time that it was. Meanwhile it must be remembered that Chiswick is still available, and if no more central site be forthcoming Chiswick would by no means be an undesirable spot, if only it were properly developed. This leads us to the question of officers. Captain BAX, who has been acting as Assistant-Secretary for some time past, has resigned. It is not necessary to enter into the reasons for this. Horticulturists will in any case have a grateful recollection of his unvarying courtesy—never too prominent a feature in the governing body of the Society—and of his willingness to oblige. Mr. BARRON and Mr. DICK still retain office, and they have, and deserve to have, the fullest confidence and respect of the horticulturists. Nevertheless, the necessity of a competent commander-in-chief, invested with full powers, and, as long as things go well unfettered by the Council, is more than ever pressing. Like Sir JOSEPH HOOKER, we do not doubt that such a man might be found. The late Mr. JENKINS, who lived to win hearty recognition from the Royal Agricultural Society for the value of his services, was quite unfamiliar with the duties of his office when he entered on his career, but he speedily made himself acquainted with them, both practical and scientific; and those who scoffed at his appointment are now among the first to admit the exceeding value of his services. We must not expect to meet with such a man ready-made—such a combination of talents as he possessed is always rare, but still there must be many a young man whose business capacity and scientific insight only need the opportunity for development. This is the sort of man the Society wants, this is the sort of man to be trusted, not thwarted, by the Council.

The list of local societies which we publish in the present issue though necessarily incomplete and only professing to be a select list, is, nevertheless, one to make the authorities of the Royal Horticultural Society ponder. Every one of those societies should be not only local, but they should be the provincial representatives of the one great National Society. The union between these local societies and the central one should be close and intimate. Each might be most useful to the other, and we hope to see in due time representatives of the more important of them, either on the Council—which would be the best plan—or, as that would be impracticable while the present charter is in existence, at least on the general committee, supposing that body to have more than an ephemeral existence. But in very truth there is no fundamental difference of opinion as to what the horticulturists want, nor as to what the general future policy of the Society should be. Details may be the subjects of difference of opinion, but we take it there is no substantial difference whatever as to matters of principle. We own that we have not any great faith in the utility of the general committee just appointed, unless the Council heartily co-operates with it. If the Council will not do this, then there is nothing for it but a new charter. If, however, the Council will carry out their part of the bargain there seems to us no absolute necessity for a new charter at present, however desirable it may ultimately prove to be. Earnestness and work are what are demanded from the horticulturists at the present juncture. If they are not forthcoming no Council, were it composed of angels, could effect much good.

THE PHOTO. SERRAVALLE & CO. 27, MARTIN'S LANE, CANON ST. LONDON, E.C.

THE FERNERY AT NASH COURT, FAVERSHAM.

FRANCOIS LACHARME.—We are requested to announce that the French Rose-growers have opened a subscription-list in order that a memorial-stone may be erected over the worthy and renowned Rose grower, FRANCOIS LACHARME, who died last November. LACHARME's name and his productions are well known to all lovers of Roses, who are invited to show their appreciation of his efforts by forwarding subscriptions for the fund to one of the Treasurers—M. A. BERNAIN, 63, Cours Lafayette, Villeurbanne, Lyon; and M. P. COCHER, Grisy-Suisnes (Seine-et-Marne). The Secretarial duties are fulfilled by M. NICHOLAS at Lyons, and M. LÉVÊQUE in Paris. The names of subscribers are to be published in the *Journal des Roses* and in the *Lyon Horticole*.

NATIONAL CHRYSANTHEMUM SOCIETY.—A meeting of the General Committee took place at Anderton's Hotel, Fleet Street, on the 5th inst., Mr. E. SANDERSON, the President, in the chair, there being a large attendance of members. It was resolved that the annual meeting of members should be held at Anderton's Hotel on Tuesday, January 31. The Secretary, Mr. W. HOLMES, announced that Messrs. WEBB & SONS, seed merchants, Wordsley, Stourbridge; Mr. C. FIDLER, seed and Potato merchant, Reading; and Messrs. H. DEVERILL & Co., seedsmen, Banbury, had offered special prizes for competition at the Society's shows at the Royal Aquarium in September and November of the present year; and the same were accepted. It was also stated that M. S. DELAUX would give the sum of 200 francs as special prizes at the November exhibition. Mr. H. CANNELL also offered valuable special prizes, conditional upon the balloting system being employed in awarding the prizes, as last year. It was generally admitted that the system broke down completely last year, and therefore a resolution was passed, almost unanimously, that the productions to be invited in competition for Mr. CANNELL's special prizes should be judged in the ordinary way. Two Fellows and seventeen new members were elected, and the Winchester Horticultural Society was admitted into affiliation. The necessity for revising the Society's catalogue of Chrysanthemums was discussed, it being stated that if it is to become as complete a list as possible of all the varieties that have been sent out from time to time, it would become not only a bulky but an expensive publication. Some were in favour of this course, others for making the catalogue a compilation of the best exhibition varieties only. Eventually the matter was postponed for further discussion.

ROYAL HORTICULTURAL SOCIETY.—At a general meeting of the Society, held on January 10, James Bateman, Esq., F.R.S., in the chair, the following candidates were duly elected Fellows of the Society, viz.:—Alfred G. Beebe, Richard Bradshaw, R. Giles Bradshaw, Henry Brown, Alex. Cheal, Miss R. Debenham, William S. Dent, T. G. H. Eley, Joseph Harris, H. Herbst, John H. Tite, John Mackrell, Frank R. Parker, Charles H. Smith.

BIRMINGHAM GARDENERS' ASSOCIATION.—At the annual meeting of this Society (January 3), in competition for special prizes offered by Mr. Wood, a member of the committee, for a collection of British grasses, to be collected, mounted, and correctly named by the exhibitor, only one collection was staged, by Mr. ALBERT JEFFS, at present groom and gardener at Boldmere, Sutton Coldfield, near Birmingham. At the commencement of 1887 he, as we are told, knew nothing whatever about British Grasses or other plants, but was induced by a friend, who lent him SOWERBY'S *British Grasses* and other works, to take up their study, and on this occasion he staged eighty-three varieties, nicely mounted and named, and won well the 1st prize, the gardeners and nurserymen present also marking their sense of his meritorious work by unanimously awarding him also a Certificate of Merit of the Gardeners' Association. This being the general meeting of the Association Mr. W. B. LATHAM was again unanimously elected as chairman of the committee. On December 6 Mr. WILLIAM

SPINKS, the manager of HANS NIEMAND & Co.'s nurseries, read a paper on "Narcissi and its Varieties," giving their classification, illustrated by coloured plates. It was a most interesting paper, and led to a spirited discussion afterwards.

"**CASSELL'S POPULAR GARDENING.**"—A new issue of this work, edited by Mr. D. T. FISH, is in course of preparation, of which the first part will be published shortly.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The following statement of the receipts and payments for the year ending December 31, 1887, is that presented at the meeting held on Friday, January 13:—

LINNEAN SOCIETY OF LONDON.—The next meeting will be held on Thursday January 19, at 8 P.M., when papers will be read:—1, "Influence of Light on Protoplasmic Movement" (part II.), by Mr. SPENCER MOORE; 2, "Studies of the Macrochlores (Humming-birds and Allies)," by Dr. R. W. SCHÜPFELDT; and 3, "New British Plants," by W. H. BERRY.

AWARDS AT THE NEWCASTLE EXHIBITION.—The committee of the Royal Mining, Engineering, and Industrial Exhibition held in Newcastle last year have awarded to W. J. WATSON, nurseryman and seedsman, Newcastle-on-Tyne, a Silver Medal for a bed of Conifers and hardy shrubs, and a Bronze Medal for a fernery and cabinet combined.

COVENT GARDEN MARKET.—At this time of year, more perhaps than at any other, choice flowers prevail. No observer looking round the market can fail to remark the preponderance of white flowers, which are naturally in great demand just now as sprays, button-holes, &c., for evening wear. There are Camellias, Eucharis amazonica, the paper-white Narcisse, Lily of the Valley, white Roman Hyacinths, Christmas Roses (Hellebores), a few late Chrysanthemums, forced white Lilacs, Azaleas, Arums, light-coloured Roses, red Pelargoniums, Carnations, Lapagerias, Bouvardias (red and white), Violets, and, of course, Orchids in season, such as Cypripediums, Dendrobiums, Ladias, Calanthes, Odontoglossums, Zygopetalums, &c. With the foregoing variety there is plenty to select from, and much with which effective combinations may be made. Arums and Eucharis, with Violets and Lily of the Valley, are greatly used for wreath-making. Of pot-plants, Cinerarias, Primulas, the various bulbous plants, Euonymus, Aucuba, berried Solanums, Ericas in variety, and Poinsettias (which have been very fluclately), form the chief supplies. Fruit consists

mainly of foreign produce, as Oranges, the Tangerine being a favourite; Bananas, Nuts of all sorts, Pomefoes, Melons, and such-like; Grapes of both English and foreign growth, and Apples and Pears, most of which are American. The supplies of American Apples have been moderate during the past week or two, and derived chiefly from Nova Scotia prices have naturally ranged high. The imported Apples, especially the better sorts sent from New York (as Newtown Pippins, &c.) have been of indifferent quality throughout the season, with a good deal of maggot present, destroying their keeping powers. Well kept English produce thus realised excellent prices this winter. Vegetables show nothing remarkable; Rhubarb, Asparagus, Celeriac, and salading, Salsify, Seakale, green vegetables in variety; also new Potatoes, green Peas, French Beans, &c., which are rather expensive luxuries just now.

MANCHESTER HORTICULTURAL IMPROVEMENT SOCIETY.—The fortnightly meeting took place on Tuesday, January 3, Mr. TARR in the chair. The President of the Society, Mr. BRUCE FIDDLAY, read a paper on the propagation of plants, which at a future time may be reproduced in part in our columns.

NORTH OF SCOTLAND HORTICULTURAL SOCIETY.—The bi-monthly meeting of the members of this Association was held in the Music Hall Buildings, Aberdeen, on Friday evening, the 6th inst., Mr. PETER HANPER, Duthie Public Park, in the absence of the President, presiding. There was a good attendance. The first paper was by Mr. OGG, gardener, Morken, on "The Fuchsia." The next paper was by Mr. SIMPSON, Dalhousie Nurseries, Broughty Ferry, near Dundee, on "Shrubs and Shrubberies."

NOVELTIES OF 1887.

In our previous issue we made some comments upon the novelties among Orchids that appeared in 1887 and now continue our remarks on other classes of plants:—

STOVE AND GREENHOUSE PLANTS.—We must commence with that fine new *Nepenthes Curtisii*, for which Messrs. James Veitch & Son were awarded a First-class Certificate on September 13, and which was described and illustrated in the *Gardeners' Chronicle*, Dec. 3, 1887. It is a grand acquisition; its pitchers large in size, noble in form, and rich in markings. *Oplismenus albidus*, of the same firm, will make a neat dwarf plant for decorative purposes; and their new double varieties of greenhouse *Rhododendron* (*R. balsaminiflorum*) are likely to obtain a large demand than the propagator can supply. In *Amaryllis* it is VEITCH also, their culture of these plants having outstripped all competition either at home or abroad. *Nerine Mansellii* is a charming rose-coloured winter flower, *Boronia heterophylla* (VEITCH) a plant to grow in quantity, and *Bouvardia President Cleveland* the most brilliant of the late Bouvardias. Ferns receive a few good additions, chiefly home raised, that successful grower, Mr. H. B. MAY, receiving Certificates for *Pteris tremula flaccida*, with elegantly elongated pinnae; *Pteris Mayii*, and *Adiantum Regine*, the latter with massive fronds, approaching *A. Farleyense*; *Pteris claphamensis* is a neat dwarf, and the *Asplenium scandens* of Messrs. James Veitch & Son, elegant and very different from any other species of the genus.

FLORISTS' FLOWERS.

Among such as are to be obtained from seed the year has been marked by a grand strain of double or semi-double Primulas of all colours belonging to SUTTON & SONS, of Reading, no less than six of which were justly awarded First-class Certificates at the Royal Horticultural Society on January 11, 1887. The value of these plants for decorative purposes and for cut flowers

at this season cannot be ever-estimated, as they are much more durable than the singles. Messrs. James Carter & Co., Mr. Cannell, and Mr. James have also during the year given evidence of their success with Primulas. The Cyclamens are kept up to their standard by Clark and Odell, the Cinerarias by Mr. James and others; and Carter's strain of Mimulus, Carter's Jubilee, as Certificated at the Royal Horticultural Society on May 20, is wonderfully beautiful and varied.

Of new plants for the open garden, noteworthy are *Delphinium Britannia*, a charming rosette flower, of pure white and dark blue, and *D. Charmant*, both of Kelway & Son; who also secured honours for some grand Gladioli, Pæonies, Gaillardias, and Pyrethrums. Of Japanese Iris, Mr. William Gordon, of Twickenham, whose collection of these and Tree Pæonies is very fine, secured Certificates for two very large and handsome varieties, viz., *I. Kæmpferi Eclipse* and *I. K. Exquisite*; and with these and Pæonies Messrs. Veitch & Son and Mr. Ware have exhibited many new kinds; and Mr. Ware has done great service to the hardy plant lovers by bringing into notice many fine plants during the past year, which, although not new, being rare, were awarded First-class Certificates. By six First-class Certificates for some grand things in the favourite and large family of Narcissus it will be seen that Mr. Barr still makes them a loving study, pleasant to trade in. The illustration in the *Gardeners' Chronicle* at p. 704, May 28, represents one of the noblest of them—*Glory of Leyden*.

Chrysanthemum Macaulay, Certificated to Mr. William Holmes, of Frampton Park Nursery, Hackney, commences a new strain, with flowers prettily crested and curled; and *C. Lord Eversley* is a grand white, not likely to fade off, with a rose tint. Enough has been said to prove that the past year has not been a barren one; let us hope that the present one will be still more fruitful in good and new plants.

FLOWERS IN SEASON.

"SPRING IS YCOMEN."—The outlook from our windows in this foggy weather certainly lends no countenance to this statement, and were it not for other evidence we might be disposed to question it. That other evidence is furnished by a rare batch of varieties of Christmas Rose from Mr. Brockbank, as well as others from Mr. Hartland, and on which we shall make further comment later on, as the lack of sunshine at present forbids our making the comparative examination which our correspondents desire. Perhaps some readers will say that the Hellebores are late autumn flowers availing themselves of the bottled sunshine of the past summer. We shall not dispute the point in this case, nor in that of the singular and beautiful *Hanamelis arborea*, with its leafless stems and purple and yellow flowers, which are so very striking at this season. This we received from Messrs. Veitch, and an illustration of it was given in our columns for 1881, vol. xv., p. 205. It is a hardy shrub, which we strongly recommend the lovers of beautiful flowering shrubs to plant in their shrubberies.

The vernal character of *Iris stylosa* is more pronounced. This we received from Mr. Hartland, of Cork. This is a charming species, with a thick rootstock, from which are sent up tufts of long linear leaves and long flower-stalks, bearing large sweet-scented pale violet-coloured flowers; the "falls" have a central orange blotch or "flame," from which radiate on each side slim purple streaks, the disc of the fall being of a deep violet. The petals or standards are paler in colour. The specimens before us differ slightly in their markings from that figured in the *Bot. Mag.*, t. 5773 (May,

1869). The plant is a native of the Greek islands and of Algeria, but, nevertheless, flowers in the open at Cork in January.

A series of flowers of seedling Hellebores from Mr. Heinemann, of Erfurt, are obviously very pretty, but neither fog nor gaslight offer adequate facilities for their inspection. We will examine them later on.

AMERICAN NOTES.

AGRICULTURAL COLLEGE OF MICHIGAN.

THE last issued *Bulletin* contains the annual report of the Professor of Horticulture, and includes detailed descriptive notices of Tomatos, Peppers (Capsicums), Onions, and Strawberries cultivated in the College grounds, together with a variety of miscellaneous information brought to light in the course of the experimental trials made under the superintendence of Professor Bailey.

THE NATIVE FLOWERS OF THE UNITED STATES.

Professor Meehan's work on this subject, the publication of which was suspended in consequence of the death of the publisher, is about to be resumed. The coloured plates and explanatory text render this a very serviceable book to our cultivators of hardy plants.

"GARDEN AND FOREST."

We understand that Professor Sargent's journal, under this title, is to appear on February 1, and be continued weekly. When the Professor was here, in the course of the last summer, he made arrangements with some of our cultivators to furnish him with news from the Old Country.

DR. A. GRAY.

We deeply regret to say that the last accounts received are of the most melancholy character. Dr. Gray, only just prior to his attack, had journeyed from Boston to Washington to take part in the election of Secretary to the Smithsonian Institute, and seemed to his friends upon whom he called in his usual health and spirits.

THE CALIFORNIA FAN PALM.

Our indigenous Palm, one of the most striking native plants of the State, gave the botanists some trouble in classification. First it was a *Prichardia*, then a *Brahea*, and finally it has found botanical rest as *Washingtonia filifera*. Its native area along the Colorado River was thrown open to the public by the building of the Southern Overland Route, and is now a comparatively familiar country. Long ago, however, seeds were brought from this region, and plants were established which have now grown to grand size, while the facts of their introduction have become a matter of tradition. The twin Palms growing within the limits of Los Angeles city are perhaps the oldest and largest cultivated Fan Palms in the State. They are probably upwards of fifty years old. These Palms are a landmark for the tourist, and their photographs are in great request. They are now being encroached upon by the buildings, and may fall before the progress of the day, but we trust they will be spared as long as possible.

The California Palm was widely distributed over the State at quite an early day. It is on record that Louis Prevost, the pioneer San Jose horticulturist, brought seed from the southern desert to San Jose about thirty years ago, and succeeded in growing about fifty plants. These were carried to all the chief points in the northern half of the State. Either from this, or in some cases perhaps from later propagations, came the large Fan Palms which are to be found at points in the Sacramento Valley as far up as Shasta county; also in Calistoga, in Sacramento, Stockton, and elsewhere.

The plant is a rapid and vigorous grower, and quite hardy. It also bears transplantation well. Some years ago the late Governor Latham bought two old Palms at San Jose. They were at the time about 25 feet high, and he is said to have paid 1000

dols. for the pair. These he moved from San Jose to his residence at Menlo Park, where they grew well, and are still standing on the old Latham place. *Pacific Rural Press.*

CULTURAL MEMORANDA.

EUCHARIS AMAZONICA.

THIS plant will now be sending up its flower-spikes. From the time of the appearance of the flower-spikes up to a few weeks after flowering the plants should have diluted liquid manure at a temperature of from 75° to 80° given them, when water is necessary. After this period water should be given only when the soil has become quite dry, maintaining this treatment till the plants again throw up their flower-stems, when the application of the tepid liquid manure should be resumed. The warm and somewhat dry atmosphere of a conservatory or reception-room will be more congenial to the requirements of the plants when in flower than that of a warm moist stove would be.

RICHARDIA (CALLA) ÆTHIOPICA.

THIS gross feeding plant pays well for liberal treatment, especially during their flowering period, from Christmas to Eastertide, during which interval, if the best results obtainable are desired, copious supplies of tepid liquid manure must be given at the roots almost daily. A minimum temperature of 50° should be aimed at, giving sufficient air during favourable weather, to prevent the plants making a weakly growth or becoming infested with aphid; but should this insect attack the plants—which it is almost sure to do—fumigate with tobacco-paper two evenings in succession, and ventilate the house more freely than usual the two following days.

BULBS, HYACINTHS, NARCISSUS, &c.

From the time the flower-spikes have attained a height of 2 or 3 inches until every pip or flower has opened liberal and frequent supplies of weak manure-water, at the same temperature as that of the house or a few degrees warmer, should be given, the soil being kept quite moist. The flower-spikes should have support.

THE FUCHSIA.

THIS is a useful and showy decorative plant, therefore a small plant or two of the most approved varieties should be put into a forcing-house to supply early cuttings, which they will do in a couple of weeks from the time of putting the plants in heat. These, when they have made 2 inches of growth, should be inserted in 3-inch pots filled with light sandy mould, watered, and the pots plunged in sawdust in a box sufficiently deep to admit of a square of glass being placed over it without coming in contact with the cuttings, placing the box over the front hot-water pipes in a forcing-house or some other suitable place; they will soon take root. They should then be potted off singly into small 60's, using a compost consisting of three parts light loam and one of sifted horse-droppings and leaf-mould with a sprinkling of sand added, returning the plants to a position near the glass in the forcing-house and watered. If the plants be afterwards attended to in the way of watering and pinching, and shifting them into larger pots before the roots get matted, they will make useful furnishing plants by the end of summer. *H. H. H.*

FRUITS UNDER GLASS.

VINERIES.

VINES on which the Grapes are thinned should receive a steady temperature of 65° at night; avoid too liberal sprinklings with water, especially during dull weather, but let sufficient be given to maintain a nice growing atmosphere. The border may require another watering, which should be applied at a temperature of 75°, and the water may just be coloured with guano. See that pot Vines have a sufficiency of water at the root, and light rich top-dressings where thinned, with occasional water-

ings with weak liquid manure, which will be of great advantage. If the fruit be required at an early date a steady night temperature may be kept up of 70° during mild weather, especially if some covering can be put over the lights.

Succession Houses.—These should be started at a temperature of 45° to 50°, a moist atmosphere being maintained by sprinkling the walls, paths, and border. During clear weather the Vines may be syringed morning and afternoon until the buds are all nicely broken. If the canes show a tendency to break irregularly, let them be tied down in a horizontal position along the bottom of the rafters; remove all the weaker shoots as soon as possible where several issue from the same spur.

Prune succession-houses as soon as the Grapes are cut, so as to rest the Vines; cut to a plump bud, making a clean cut with a sharp knife, twelve hours after dressing the wounds with Thomson's Styptic. Unless the Vines are infested with bug do not strip off more of the bark than is loose, or will become detached by passing the hand lightly round the stem.

Scrub the stems and spurs with a spoke-brush, using warm water, a little soft-soap, and a small quantity of petroleum, which will clear them of red-spider. Well wash all the glass and woodwork, whitewash the walls with quicklime and flowers of sulphur, and, if practical, a coat of paint should be given to the inside of the fruit-house every year. This allows of a fresh start, without much danger from insects.

The stems of the Vines may be painted over with soft-soap, sulphur, and tobacco-water, and be thickened with clay to the consistency of paint. If mealy-bug has effected a lodgment, the spurs and stem must be scraped, the wood washed several times with water strongly impregnated with petroleum, and be painted over with coal-tar and water (clear) equal parts thickened with clay: the mixture must be kept constantly stirred while it is being applied else serious injury may be done to the Vines. Remove the top soil down to the roots of the Vines, and well dust with Vine manure, re-surfacing with fresh loam and charred soil. Should there be an absence of lime in the soil, a few lumps of lime may be slaked on the border and the fine powder scattered evenly over, and pricked into the surfacing. A sufficient number of Vine eyes may now be put into small pots or on turves to strike, the latter being the preferable mode, as the roots do not get cramped. The stock of Grapes hanging on the Vines will require frequent looking over and all mouldy berries removed. Maintain a temperature of 40° to 45°, and be careful in admitting air in wet and foggy weather. Those which have been cut from the Vines and are kept in the Grape-room—which should be perfectly dark and kept at an unvarying temperature of 45°—will give little or no trouble, if the Grapes were well finished on the Vines. *W. M. Baillie, Luton Ho.*

THE KITCHEN GARDEN.

CROPPING.—Arrangements for the principal crops during the ensuing season should now be completed, and the ground should be prepared in accordance with their requirements. A rotation of crops should be, as far as possible, secured; a plan of the garden, with the various plots numbered, is of great service in such matters, and a cropping book with columns ruled for dates of sowing, transplanting, maturity and duration of crops, and space for remarks on the varieties, should also be kept. It is necessary to have the plot for Onions made ready in good time, by having the ground well worked and pulverised before the arrival of sowing time. A more liberal supply of manure is essential for this crop than for some others, and an open position should be afforded it. Root crops should as a rule follow a crop of another character that has been heavily manured, such as Celery, the ground to be deeply worked, but no manure given. A deep and well pulverised soil, tolerably free from large stones, is one of the chief points in root culture. A warm, sheltered position should be reserved for the earliest plot of Potatos, for which a good dressing of charred refuse, either with or without farmyard manure, will be beneficial.

General Work.—During mild weather all vacant ground should be dug over as soon as possible, laying it up roughly to be disintegrated by frost. Where any ground is intended to be trenched—and a portion of the garden should be done every year—it may be taken in hand during frosty weather if the

manure has been previously spread over the surface; but snow should never be dug into the ground. Fresh plantations of Horse Radish may now be made, trenching the ground 2 feet deep. Make the holes with an iron bar, and push the sets to the bottom. Take advantage of any mild weather to examine outdoor Mushroom beds, returning the covering again as quickly as possible. Continue to collect and prepare material for succession beds, keeping it secure from rain and snow. Replenish stores of Celery, Brussels Sprouts, &c., during mild weather, and take the hearts out of Scotch Kale to throw the strength of the plants into the sprouts. A sufficient quantity of fermenting material should be prepared for forcing Potatos, Carrots, and Turnips, utilising brick pits with a flow and return hot-water pipes for the earliest crops, or a hole may be dug out deep enough to hold most of the fermenting material necessary, and a frame put on this about 2 feet above the ground level. A sufficient number of Potato sets should be placed in shallow boxes with a little leaf-soil over them, and be put into a temperature of 50° to start into growth: Veitch's Improved Ashleaf, or the old Walnutleaf, are still good varieties for early forcing. All other sets of early Potatos should by this time be arranged thinly on shelves before growth gets far advanced. *W. H. Divers, Kelton Hall.*

HOME CORRESPONDENCE.

Correspondents will greatly oblige by sending early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Photographs or drawings of gardens, or of remarkable plants, trees, &c., are also solicited.

NEW VARIETIES OF POTATOS.—In reply to "North Norfolk," p. 23, in the last issue of *Gardeners' Chronicle*, I can very strongly recommend to him the following two kinds, after having given them a three years' trial, as being first-class in every way:—Welford Park is a handsome white main crop variety, with large tubers, a heavy cropper, smooth skinned, and well-formed, with good quality and constitution, and so far it has been free from the disease. It boils of good colour. Miss Fowler is a first-class handsome late white kidney, of medium-size tubers, a heavy cropper, also free from disease, robust in constitution, and cooking well. These two new Potatos were sent out by Messrs. J. Veitch & Sons, Chelsea. If "North Norfolk" will send me his address I will send him a few of each kind for trial. *Wm. Smythe, The Gardens, Basing Park, Alton, Hants.*

"North Norfolk" (p. 22), will doubtless have plenty of advisers, and possibly be bewildered by the multitude of counsels. It is very difficult to advise fairly in the matter of kinds of Potatos for diverse soils and districts, because these products are peculiarly sensitive to soil differences; and that fact invariably handicaps advice. None the less I think the enquirer will find satisfaction in such a sterling variety as Prime Minister, which is a robust grower, heavy cropper, tubers white, long, flattish, and of real Regent-like texture; Abundance, flattish round white, very robust and heavy cropper; The Dean, purple round, strong grower, heavy cropper, flesh yellowish, flaky, and fine flavoured; and Chancellor, flattish white kidney, very heavy cropper, stout, erect, woody stalks, and a very fine winter variety. Of these, probably The Dean is the best flavoured, but here all are capital. Still, Middlesex has a good reputation for the production of Potatos, whilst "Norfolk" may have inferior soil. Would he not be wise to occasionally change the seed of the kinds he has named, or at least of those to be had? There must be in the soil something peculiarly demoralising to Potatos to render kinds, good elsewhere, so pasty, soft and tasteless. Very likely liberal additions of phosphatic manures, such as kainit and soot, would be very helpful to the soil. Potatos must find in soils their essential constituents or otherwise they will be of poor quality, irrespective of sort, whilst the blame is laid upon the sort rather than upon the soil. I have great faith in phosphatic compounds as cultural Potato constituents. *Alex. Dean.*

GROWING ORANGES.—I noticed in the *Gardeners' Chronicle* of December 31 a correspondent writing about an Orange tree bearing fifty-six fruits. I send you as a sample four Oranges gathered six weeks ago from a tree, which is carrying seventy-nine

good-sized ripe fruits; in a green state upwards of eighty. The fruit was exhibited in the Oxford market at Christmas, and attracted much attention. Insects do not attack the tree. *J. Mayo, St. Mary's Road Nursery, Oxford.* [The fruits were large and showy, and being the Seville variety, or else a wilding, were very suitable for the making of marmalade. Perfectly good edible kinds are as easily grown as the worst, but to ripen them properly, an intermediate temperature is required. *Ed.*]

THE ROYAL HORTICULTURAL SOCIETY.—The letter from so eminent and experienced an authority as Sir Joseph Hooker, in your last issue, has such a decided and practical ring about it, that it is my own opinion that no time should be lost by the Council of the Royal Horticultural Society in their efforts to carry out his advice. I am not a Fellow of the Society, but I, as an Associate, take a real and earnest interest in its present condition and future welfare; nor is this keen interest merely an individual one, for I am sure that the majority of gardeners in Great Britain and Ireland would flock to the standard of the Royal Horticultural Society, if a standard-bearer or Secretary worthy of their confidence be found. The general idea now is that the Society should retain its charter, or supplant it by a new one, but that in any case the garden at Chiswick should be retained. Most of us look upon the Chiswick garden and the Lindley Library as the anchors to which our horticultural *Great Eastern* is at present safely moored. The real *Great Eastern* may be useless and best as broken up, and her available materials employed over again in some useful and profitable way, but we cannot say this of our own good old ship, which is as potent for good work as ever, if only that she be promptly and ably manned. We must really take Sir Joseph Hooker at his word, and the Royal Horticultural Society must revert to her old practice, and be replaced in a position of independence and usefulness. "It is not horticulturists only whose sympathies are enlisted in the present movement, but botanists and agriculturists" as well. No truer words were ever spoken than are these! The modern depression in agriculture and its products, the storm warnings of foreign competition, and the widely extended cultural practice of our neighbours on the Continent all point out to us that the future of profitable farming will be in reality "gardening in the fields." An acre of Violets or of Christmas Roses, on suitable soils, and in well-selected positions, is to-day far more profitable than either corn or meat culture. Even the large market gardens near London and other great towns do not pay so well in proportion to the returns as do the little glasshouse gardens, wherein the choicest of fruits, vegetables, and flowers are grown. I say grown; but the precision with which the specialists develop their crops under a glass roof is so fixed and sure, that one might almost think that manufacture, or "made by hand," a better term. In a word, cheap transit rates by steamers and the cheapness of imported products have struck a death-blow at all rough and ready farming pursuits—the skilful practical gardener can, and often does, step in and succeed on land whereon the farmer has totally failed. When I say that flowers of the best and choicest pay better than cattle or corn culture generally, I of course do not forget the weak point in the illustration, viz., that the corn and cattle actually support and produce a real quantity of human life, while the flowers merely ameliorate and smoothen life's road; still, so long as people need more than bread alone—so long as taste and mind-culture crave the best the vegetable world affords, so long is the success of the real and able gardener fully assured. Chiswick, then, must be retained at all costs, and central and permanent meeting rooms in London are to be and must be, obtained. This much is in reality a foregone conclusion. Then comes the question of a permanent and well-paid Secretary. It is certainly not easy to get botany and business-knowledge combined, and I should suggest Professor Henslow for the botany, and some good business man of experience to manage the Society's affairs. The best investment the Council can ever make is to obtain an official or officials of the kind suggested in Sir Joseph Hooker's letter, and I believe there are now amongst the Kew staff and elsewhere more than one man eminently fitted for such a responsible post. Wherever the Society's rooms and the library may be it is a *sine qua non* that they be open daily from, say, 10 until 4, for the use of Fellows and their friends. It is a question whether either amateurs or nurserymen would entrust their rare plants to the Society's care

on ordinary days; but there might always be cut specimens in fresh water duly labelled, and some fruits and vegetables lend themselves most conveniently to permanent exhibitions of this kind. The Lindley Library would become much enriched by the contributions from authors, or the publishers of horticultural works if it became known as the recognised meeting place, as suggested by Sir Joseph Hooker. In my opinion, and in that of others whom I have consulted in this matter Sir Joseph Hooker's letter has really brought the present necessities of the Society to a focus. I presume he never mentioned the Chiswick garden because of the well-known impression on all sides that it must be retained as a sort of sheet-anchor. I would now beg to suggest that the Council summon a meeting, and that the essential points in the letter be officially confirmed. F. W. Burbidge, F.L.S., A.R.H.S.L., University Gardens, Dublin.

The publication of the list of members of the new Fruit and Floral Committees seems to justify my references last week to the necessity of some official explanation of the grounds upon which new appointments are made. Mr. W. Marshall, one of the most efficient chairmen of the Floral Committee that body ever had, must laugh comically when he finds himself pitched into a round hole on the Fruit Committee; as also must Mr. J. Wright, the second representative of the *Journal of Horticulture* on that body. On the other hand, Mr. Wildsmith and Mr. Bates, two excellent fruit growers, will feel strangely out of place on the Floral Committee, unless the Orchid men have specially striven to weaken the genuine floral knowledge of the committee, for the former held literally one-half the seats on the committee—rather an excess, when it is remembered that the bulk of these know little and care less about other flowers. Which of the new appointments can, for instance, make good the void created by the loss of Mr. J. Douglas, whose knowledge of other flowers equalled, probably excelled, that of all the other Orchid men put together? The arrangement of appointments seems to be a terribly defective one, which removes such unique knowledge as that of Mr. Douglas in the one case, and Mr. Bunyard in the other, and replaces them by—whom? And echo answers, "Whom?" Spade.

THE DUKE OF BEDFORD AND COVENT GARDEN MARKET.—Under this heading Miss Slaymaker, of Covent Garden Market has contributed a letter to the *Weekly Times and Echo*, which sets forth in a striking light the anomalous and uncertain tenure upon which shops in the centre row are held from the Duke of Bedford. She states:—"Forty-three years ago my father became tenant of one of the shops in the Central Avenue, Covent Garden Market, at a weekly rental of 35s., he paying the outgoing tenant £100 for the business of a fruiterer and florist, and spending a large amount in improving the premises. At his death, about fifteen years ago, my mother was accepted as tenant at the same rental. I (her only daughter) have always assisted in the business, and, for some years past, my mother's health failing, I have had the sole responsibility, employing a trustworthy man as manager. On the death of my mother in April last I applied to the Duke's steward for the tenancy of the shop. I was told that even if accepted as tenant, which was doubtful, I should have to pay £4 10s. a-week rent, and should be allowed to use the premises as a fruiterer's only, and also dismises from my service my manager, who has been with me twelve years. I accepted the shop under protest, but feeling very insecure under such a landlord, I have since taken premises in Catherine Street, opposite Drury Lane Theatre, and am endeavouring to transfer my business from the market there. Is it not hard that the Duke should be thus able to deal with the daughter of a tenant of forty-three years' standing who is working hard to get a living?" From this letter it appears there is no such thing as security of tenure in Covent Garden Market, and that the regulations enforced by the ground landlord appear to be in defiance of the simple rules of equity. In this case it would appear that the ground landlord can do what he likes with his own, and also in what appears on the face of it to be a high-handed and arbitrary fashion. R. D.

THE HONEY TRADE.—I wish I could see my way to join in equally cheerful terms with your correspondent, Walter Chitty, on the honey trade. I recently submitted a sample of some of the best comb honey I have ever had in my limited experience, to a certain company founded some few years ago, and the

best price they could offer me was 7s. per dozen 1 lb. sections, delivered free and unbroken in London—practically 6d. per pound; and this is the company that was to find a market for all our amateur beekeepers' produce, and was to be the salvation of the cottager whose industry included beekeeping as a means of making a little extra out of his rural surroundings. If British honey is so much superior, and is being so much appreciated, surely a pound of a good sample should command a little more in the market than the "little bottles of something supposed to be honey" seen in our grocers' windows. Let us hope with Walter Chitty that a brighter future is in store for beekeepers. An Amateur Beekeeper.

RAINFALL AT WARWICK.—The following is the report of the rainfall for the past year. Last year was an exceptional one in character, and the rainfall less than usual. The diameter of the funnel of the rain-gauge is 5 inches, the height of the gauge above the ground level is 4 feet 2 inches, and above the sea level 240 feet.

R. Greenfield, Priory Gardens, Warwick.

FREESIAS.—Will any one who has had experience with these plants tell me the reason why mine have not grown. The following is the treatment given:—The bulbs were bought in 1886, and I grew them in a greenhouse with a south-eastern aspect, keeping them near to the glass. The compost consisted of loam and leaf-mould with a portion of silver-sand, and they all grew and bloomed to perfection. When they had finished blooming I put them in a cool place, where they were dried off. When the tops were all dead I shook them out and put them into flower-pans, keeping them in a seed cupboard until the beginning of September, when I potted them in the same kind of soil as before and put them in the same place as they were in during the previous year. The bulbs are of good size and perfectly sound, but this year the greater portion of them have not grown. I cannot see why they have not developed. Those that did start are now showing the blossoms. R. H. L.

THE BEST TWO GARDEN PEAS.—If all but two of our varieties of Peas were swept away, which should be maintained? I think the two best all-round varieties—good reliable croppers and general favourites—are Veitch's Perfection and No. Plus Ultra. I am estimating their value as garden Peas, not for exhibition purposes. Both are of high quality and flavour, though No. Plus Ultra would perhaps gain two or three points over Veitch's Perfection in this respect. There are plenty of exhibition Peas—varieties that can be richly grown, stopped and thinned, in order to have large and showy pods, with a fine bloom upon them; but it is very doubtful if any of them will become standard varieties. If two-thirds of our so-called garden varieties of Peas were swept away, and never seen again, the loss would be a gain rather than a calamity. It will be said, Veitch's Perfection should give place to an earlier variety; but by sowing early Veitch's Perfection can be had much earlier than is generally supposed; and of our first early varieties, who shall name one that will compare with Veitch's Perfection for table quality? *Daring*.

PLANTING TREES AND SHRUBS.—At the outset, and before a commencing with planting work, the first question to be asked is what should be planted?—taking into consideration the soil, climate, and

situation. Where this is done errors of judgment seldom occur. As regards the question what to plant, the best guide will be found by observation of the trees and shrubs of the surrounding district, and to select only those subjects which flourish. It may happen that there is a desire to plant something new, i.e., new in the sense of its not being known to grow in the locality—for the sake of variety; and when this is the case it is advisable to use caution, and plant sparingly at first in diverse situations, and in a few years their adaptability or the reverse may be readily noted. When the soil only is unsuitable to the growth of any kind of tree it may be made of a suitable nature. In the laying out of new grounds all clumps and borders, together with larger areas coming under other designations, should, previous to planting, be well drained where necessary, and trenched over to a depth of not less than 18 inches, and if the ground is in anything like a poor condition a dressing of well decayed manure will be found very advantageous. J. Horsfield, Heytesbury.

THE GOOSEBERRY CATERPILLAR AND RED-SPIDER.—I am desirous of finding a substance that will kill red-spider and the caterpillars that infest Gooseberry bushes, without injury to the plants. I grow hardy fruits extensively, and these were so badly infested with red-spider last season that I dread its reappearance this year. I dusted some of the trees with quicklime, which had no effect on the caterpillars. Have any of your numerous correspondents tried superphosphate of lime or rag-dust as a remedy, or any other substance that will destroy spider and caterpillars? If so, the publication of its name would be a great boon to cultivators. As I grow acres of Gooseberries the syringing with soft-soap and tobacco-water is too slow a process to be done in a reasonable time, and when done is not effectual. William Clarke, Fruit Grower, Hemingford [It was stated in the *Gardeners' Chronicle*, June 25, 1887, that Mr. Samuel Barlow, Stakehill House, Castleton, Manchester, contributed an interesting paper in the *Agricultural Gazette* on the "Use of Superphosphate of Lime to Destroy Fly on Turnips," which answered the intended purpose admirably; and it was further stated that the application to slugs on other plants was equally effective. The superphosphate used was the ordinary 25—28 soluble. En.]

PICEA AJANENSIS.

We have so frequently spoken of this very beautiful and hardy flat-leaved Spruce that we should hardly be justified in alluding to it again, were it not for the opportunity now afforded of figuring a cone which was produced in Mr. Waterer's nursery at Woking, and which differs considerably in the shape of the bract and cone-scales from *P. Alcockiana*, which name it bears in some gardens, though it differs materially from that species. (Fig. 10).

The great features of *P. ajanensis* are its hardness, its dense pyramidal habit, its flattish leaves silvery on the upper surface, as in Junipers, rich green on the lower, and its very beautiful orange-crimson male flowers.

This is decidedly one of the very best hardy Conifers introduced into English gardens by the late Mr. J. G. Veitch, and it is surprising that it is not more often met with. Illustrations of this species were given in our columns January 24, 1880, and October 2, 1880.

SOCIETIES.

ROYAL HORTICULTURAL.

TUESDAY, JANUARY 10.

Floral Committee.

Present: G. F. Wilson, Esq., F.R.S., in the chair; and Messrs. W. Wilks, H. Bennett, H. Herbst, W. Bates, G. Nicholson, W. Goldring, R. Dean, J. Dominy, H. M. Pollett, C. Noble, H. Ballantyne, B. Wynne, J. O'Brien, E. Hill, and G. Duffield.

The contribution from Messrs. J. Veitch & Sons, Chelsea, formed the interesting feature of the show on this occasion. Hybrid Rhododendrons were represented by plants in flower, and also by cut trusses of bloom. One of these hybrids, named Primrose from its colour (the result of *R. Teysmanni* × *R. (hyb.) Maiden's Blush*), was very attractive, and received a Certificate. Eclatant, with rich red coloured flowers, is also effective, and the result of crossing

jasminiflorum with Curtisii is a bright deep red. These hybrids are remarkably pretty, and it is to be regretted that they are not more free in flowering. There also came from the same source *Cypripedium Galatea* ×, a hybrid of uncertain parentage, with a large flower somewhat resembling *C. insigne*, but much paler. The markings on the dorsal sepal were green heavily spotted with red-brown, the spotting extending all over the flower; the ground colour of the lip was yellowish-brown; the colouring of the lateral sepals was divided by the midrib of the sepal, the upper half being dark, the lower of a lighter hue. A hybrid *Phalenopsis* (*amabilis*, Bl. × *intermedia* Portei), named *F. L. Ames*. The sepals and petals are white, while the lip is attractively coloured, the lower portion of the middle lobe being rose on yellow, the upper portion rose on white. The lateral lobes are white suffused with rose and reticulated with the same colour; at the base there are purple spots. The plant bore several blooms.

A graceful Orchid (*Angraecum Sanderianum*) came from Messrs. F. Sander & Co., St. Albans. The specimen bore two racemes, each bearing about twelve flowers of pure white, and about three-quarters to 1 inch in diam., the tail measuring about 3 inches in length.

A finely flowered large piece of *Cypripedium insigne* was shown by Mr. J. Quarterman, gr. to A. S. Smith, Esq., Cobham. There were about fifty blooms on the specimen.

Four charming *Cypripediums* were shown by F. G. Tautz, Esq., Studley House, Shepherd's Bush (gr. Mr. P. Cowley). They were *C. plunerum*, with the dorsal sepal whitish, marked with very dark green nerves; lateral sepals similar, but with rose suffused, which colour becomes intense at the apex (see *Gardeners' Chronicle*, January 8, 1887, p. 41). *C. Marshallianum*, a peculiar spotted form (illustrated April 16, 1887) creamy-rose ground colour spotted purple. *C. concinnum* and *C. Tautzianum*, which latter is a great acquisition. The entire flower is almost of one colour, viz. rich rosy-crimson. The dorsal sepal is almost triangular, with nerves which are very dark rosy-crimson. The parentage is *C. barbatum* × *C. niveum*.

Messrs. H. Low & Co., Clapton, sent *Angraecum calligerum*, a species with yellowish-white flowers about 1 inch in diameter.

Flowers of *Laelia anceps* Schroderae were sent by Baron Schroder, The Dell, Egham (gr., Mr. Ballantyne); it is a very taking form, and brilliantly coloured. The sepals are pale rose, petals darker, with deep purple tips; deep rich crimson lip bearing a yellow crest, and internally marked with purple and yellow stripes.

A. H. Smece, Esq., The Grange, Wallington, Surrey (gr., Mr. Cummins), showed three Orchids—*Laelia anceps* Protheroianum, rather deep rose-coloured throughout, and the lip veined with yellow; *Epidendrum polybulbon*, a minute species with pseudobulbs three-quarters of an inch in length; sepals and petals one-third of an inch in length, golden-yellow at the apex, rich brown at the base; the lip white and large—a very pretty little species; also *Odontoglossum Rossi Smeceanum*, differing from the type by not being spotted with brown.

Mr. M. Simpkins, gr. to R. J. Measures, Esq., Flodden Lodge, Camberwell, sent *Cypripedium Salieri* (a fine specimen), *C. apiculatum*, *C. regale*, and *C. Forsterianum*—this is a dwarf form, with the margins of the sepals curled; colour greenish-yellow, spotted brown.

An excellent display of well-grown *Primulas* was that set up by Messrs. H. Cannell & Sons, Swanley; most of the varieties have been observed at exhibitions and in private establishments, but as yet are by no means common—not even the Burghley seedlings, which deserve to be found everywhere. The following are the names of a few of the finest varieties observed:—*White Perfection*, Swanley Giant, a pale rose coloured flower of fine form; *Cannell's White*, also excellent; the flesh-coloured *Princess of Wales*, *Eva Fish*, a mauve-coloured flower edged with white, semi-double—is sure to be a favourite when known; *King of Purples*, a brighter pink than *Earl of Beaconsfield*, but of similar form, and probably hailing from Burghley. *Marchioness of Exeter* was well shown; it is still one of the best of the white doubles. A Silver-gilt Banksian Medal was awarded.

Mr. J. James Woodside, Farnham Royal, Slough, showed a box of *Primula* blooms of large size and good colours. A large show of *Cyclamens* was made by Messrs. Page & Son, Teddington: the plants were vigorous and well flowered, and the colours pure and bright; some of the dark reds were very fine. The

strain is evidently a good one. A Silver-gilt Banksian Medal was awarded.

Mr. F. Ross, gr. to Sir G. MacLeay, K.C.M.G., Pendell Court, Bletchingly, Surrey, showed a flowering branch of *Oxera pulchella*, a woody climber, native of New Caledonia, and succeeding well in a warm greenhouse. This is evidently a free flowerer, bearing clusters of pale greenish-white flowers producing a pleasing and light effect.

FIRST-CLASS CERTIFICATES.

To Messrs. H. Cannell & Sons, for *Primula* (double) *Miss Eva Fish*.

To Messrs. F. Sander & Co., for *Angraecum Sanderianum*.

To F. G. Tautz, Esq., for *Cypripedium Tautzianum*.

To Baron Schroder, for *Laelia anceps* Schroderae.

To Messrs. James Veitch & Sons, for *Phalenopsis F. L. Ames*.

To Messrs. J. Veitch & Sons, for *Rhododendron Primrose*.

To Mr. F. Ross, Pendell Court, for *Oxera pulchella*.

FIG. 10.—PLECTRA ATAYENSIS.—CONE, BRACT, SEED SCALE AND LEAF SECTION, THE LATTER MAGNIFIED.

Fruit Committee.

Present: Dr. R. Hogg, in the chair; and Messrs. W. Marshall, C. Howe, C. Ross, A. H. Pearson, J. Wright, G. T. Miles, G. W. Cummins, J. Cheal, J. Woodbridge, H. J. Veitch, J. Roberts, P. Crowley, T. F. Rivers, J. Lee, R. D. Blackmore, P. Barr, H. Weir, and G. Norman.

The duties of the committee were of the lightest character, the exhibits being very small in number.

Mr. J. Roberts, gr., Charleville, Tullamore, showed two specimen bunches of his white seedling from Gros Colmar, which were small and compact, the berries of a medium size, and the colour greenish-yellow. It was figured in these pages, and our opinion of it has not been modified in the interval.

Seedling Apples were shown by Messrs. J. R. Pearson & Son, Chilwell, Notts; and by Messrs. Barron & Sons, Nurseries, Elvaston, in both cases showy fruits, but not of sufficient merit to be worthy of a certificate.

A dish of the Royal Medlar was sent by Messrs. T. F. Rivers, Sawbridgworth; it is a small fruit of a sweet taste, and is said to be superior to the common forms and to make an excellent preserve.

A curled Kale from Messrs. Hurst & Sons, Houndsditch; and some Tomatos from Mr. E. Newton, Hitchin, completed the exhibits in this division.

FIRST-CLASS CERTIFICATE.

To Messrs. T. Rivers & Son, for Medlar Royal.

THE NATIONAL CHRYSANTHEMUM.

WEDNESDAY AND THURSDAY, JANUARY 11 AND 12.—The midwinter meeting of this Society took place at the Aquarium on the above-mentioned dates, and was productive, for the time of year, of a display of the Chrysanthemum which would not have been thought possible a few years ago. There was nothing of very great merit, but the possibilities of Chrysanthemums in January were made apparent.

The nursery trade was represented by several London and provincial firms, the best show—one of *Primulas* and *Cyclamens*—being made by Messrs. Sutton & Sons, Reading, who covered a great extent of tabling with well-grown and flowered plants. Novelty in this collection consisted of *Primulas* *Picotee-edged*, a pink and white variety, and *Giant Red*; and in *Cyclamens* *White Butterfly* and *Sutton's Queen of Dwarfs*. The *Cyclamens* were in every way wonderful examples.

Messrs. H. Cannell & Sons, Swanley, had a more numerous collection of *Primulas* than they had exhibited at South Kensington on Tuesday, and showed the same new varieties for Certificates. As a recognition of the superiority of this collection a Certificate was awarded, together with a 1st prize.

Messrs. H. Page & Son, Grove Nursery, Teddington, showed a large bank of *Cyclamen*, dwarf and well grown. A Silver Medal was awarded.

Mr. R. Clarke, florist, Twickenham, showed *Cyclamens*, but the plants were sparsely bloomed.

Mr. H. Williams & Son, Fortis Green, exhibited a collection of *Primulas*, and another of forced flowers and foliage plants, both good in their way.

Mr. John May, Gordon Nursery, St. Margarets, Twickenham, had a large number of *Cyclamens*—*May Queen*, a large white and purple flower; and *Black Prince*, an exceedingly dark variety, being the most novel.

Chrysanthemums were shown in collections of cut blooms by Mr. G. Stevens, St. John's Nursery, Putney; Mr. J. Lowe, nursery, Uxbridge; Mr. R. Owen, Floral Nursery, Maidenhead; Mr. J. Walker, nursery, Thame; and Mr. G. Brand, nursery, Winchmore Hill.

In the amateur classes Mr. R. Jameson Hessle, Hull, was 1st for twenty-four Chrysanthemum blooms. Mr. Kipling, gr., Knebworth, Herts, was 1st for twelve blooms. In each of these classes there were six lots shown of varied merit. Mr. Sullivan, gr., Downshire House, Roehampton, was the winner with twenty-four Japanese, and Mr. Kipling was 1st with twelve Japanese.

The small classes were better contested than the larger, and here Messrs. W. & G. Drover, Fareham, took the 1st prize for six Japanese, showing several fair blooms of their novelty—Mr. W. Drover, a very fine and distinct variety, with large full flowers, somewhat incurved, and of a pale fleshy-pink colour.

The best single variety of Chrysanthemum was that of Mr. R. Brocklebank, shown by Mr. J. Winkwork—a flower of medium size and fairly full.

Some exceedingly well berried specimens of *Solanum* were shown by Mr. P. Conish, gr. to J. Dominy, Esq., The Shrubbery, Enfield.

Of subjects submitted to the committee for examination First-class Certificates of Merit were awarded to Mr. May, St. Margarets, Twickenham, for *Cyclamen persicum grandiflorum* *May Queen*, a fine light variety of the *persicum* type, with large, stout, and well-formed flowers. To Messrs. W. & G. Drover, nurserymen, Fareham, for Japanese Chrysanthemum *William Drover*. To Mr. T. S. Ware, Hale Farm Nursery, Tottenham, for Governor of Guernsey, a pale golden-yellow variety, something in the way of *Peter the Great*, good habit, and very fine; certificated as a late-flowering decorative Chrysanthemum. To Messrs. Henry Cannell & Sons, nurserymen, Swanley, for *Primula sinensis* *Miss Cannell*; and for double *Primula sinensis* *Eva Fish*. To Messrs. Sutton & Sons, seed merchants, Reading, for *Cyclamen Queen of Dwarfs*, and also to *White Butterfly*, two charming and distinct white varieties; to *Primula sinensis umbriata* *Giant Red*, with large and finely formed reddish-purple flowers; and to *P. s. Picotee-edged*. *Scarlet Fern-leaved*, the first scarlet flowered in the *Fern-leaved* foliage, it is said, was commended. A white-flowered sport from Chrysanthemum Mrs. C. Carey, named *Christmas Beauty*, sent by Mr. W. R. Strong, Wellington College, was regarded as promising; and a yellow sport from *Mrs. Merrilies*, from Mr. Kipling, the committee desired to see again.

A LIST OF SOME OF THE PRINCIPAL
HORTICULTURAL SOCIETIES, &c.,
IN THE UNITED KINGDOM;

WITH NAMES AND ADDRESSES OF SECRETARIES.

- ABERDARE HORTICULTURAL—
Sec., D. P. Davies, 17, Commercial Street, Aberdare.
- ACTON HORTICULTURAL—
Hon. Sec., W. T. Powell, 15, Mill Hill Road.
- ALNWICK HORTICULTURAL AND BOTANICAL—
Hon. Secs., G. Simpson and J. Ferguson, Alnwick.
- ASCOT, SUNNINGHILL AND DISTRICT HORTICULTURAL—
Sec., Geo. Watkins, Hill House, Ascot.
- ATHERSTONE HORTICULTURAL—
Hon. Sec., Alfred Sale, Atherstone.
- AYLESBURY FLORAL AND HORTICULTURAL—
Sec., W. Elliott, Aylesbury.
- ALVERSTOCK AND GOSPORT CHRYSANTHEMUM—
Sec., J. Mitchell, Cemetery Lodge, Ann's Hill, Gosport.
- BAGSHOT AND WINDLESHAM ROSE—
Sec., T. W. Girdlestone, Sunningdale, Berks.
- BANBURY CHRYSANTHEMUM—
Hon. Sec., F. G. Day, Banbury.
- BANBURY HORTICULTURAL—
Sec., A. Westland, jun., Banbury.
- BANFESHIRE HORTICULTURAL ASSOCIATION—
Sec., Anthony A. W. Gordon, Banff.
- BASINGSTOKE HORTICULTURAL—
Hon. Sec., H. Loe, Wote Street, Basingstoke.
- BATH FLORAL FÊTE AND BAND COMMITTEE—
Sec., B. Pearson, 14, Milson Street, Bath.
- BATH AND WEST OF ENGLAND AND SOUTHERN COUNTIES ASSOCIATION—
Steward, Hon. and Rev. J. T. Boscawen, Lamoran.
- BEDFORD AND BEDFORDSHIRE—
Hon. Sec., H. Tebbs, Stoneleigh, Bedford.
- BEDFORD CHRYSANTHEMUM—
Sec., J. Sanders Clarke, 49, Linden Road, Bedford.
- BEDLINGTON HORTICULTURAL—
Sec., R. Redpath.
- BERMONDSEY ("PIONEER," SOUTH) AMATEUR FLORAL—
Hon. Sec., W. J. Lashbrooke, 47, Beatrice Road, Southwark Park Road, S.E.
- BILSTON HORTICULTURAL—
Hon. Sec., C. T. Morell, Swan Bank, Bilston.
- BIRMINGHAM AND MIDLAND COUNTIES CHRYSANTHEMUM—
Sec., T. Hughes, Northwood Villas, Metchley Lane, Harborne, Birmingham.
- BIRMINGHAM BOTANICAL AND HORTICULTURAL—
Sec., W. B. Latham, Botanical Gardens, Birmingham.
- BISHOP'S WALTHAM HORTICULTURAL—
Sec., E. Molyneux, Swanmore Park, Bishop's Waltham.
- BLANTYRE HORTICULTURAL—
Sec., James Jackson, Old Place, Blantyre.
- BLYTH—
Sec., R. Tait, Blyth.
- BOROUGH OF TYNEMOUTH HORTICULTURAL—
Sec., J. F. Spence, jun.
- BOSTON FLORAL AND HORTICULTURAL—
Hon. Sec., J. G. Killingworth, Boston.
- BOURNEMOUTH AND DISTRICT CHRYSANTHEMUM—
Hon. Sec., J. A. I. Sola, Deepdale, Surrey Road, Bournemouth.
- BRADFORD CHRYSANTHEMUM—
Hon. Sec., J. Collier, 10, Mainham Road, Manningham, Bradford.
- BRENTWOOD HORTICULTURAL—
Hon. Sec., G. P. Charter, Brentwood.
- BRIGHTON AND HOVE CHRYSANTHEMUM—
Sec., M. Longhurst, 18, Church Road, Hove.
- BRIGHTON AND SUSSEX FLORICULTURAL AND HORTICULTURAL—
Sec., E. Carpenter, 96, St. James' Street, Brighton.
- BRISTOL CHRYSANTHEMUM—
Hon. Sec., Alfred Polkinghorne, 96, Egerton Road, Bishopstone, Bristol.
- BROCKHAM AMATEUR ROSE—
Hon. Sec., Rev. A. Cheales, Brockham Vicarage, Reigate.
- BROMLEY (KENT) DISTRICT CHRYSANTHEMUM—
Sec., J. Shortland, Sunnyside, Bickley, Kent.
- BROUGHBY FERRY HORTICULTURAL—
Sec., Thomas Buick, Camphill Cottage, Broughby Ferry.
- BURY ST. EDMUND'S AND WEST SUFFOLK HORTICULTURAL—
Hon. Sec., P. Grieve, Bury St. Edmunds.
- BUTE HORTICULTURAL, ROTHESAY—
Sec., Robert Fyfe, Bute.
- CAVNE (WILTS) HORTICULTURAL—
Sec., — Harris, Cavne.
- CAMBERWELL AND PECKHAM AMATEUR FLORAL—
Sec., J. Hall, 18, Camden Grove North, Peckham, S.E.
- CANTERBURY AND KENT ROSE—
Hon. Sec., Rev. H. B. Biron, Lympe Vicarage, Hythe, Kent.
- CANTERBURY HORTICULTURAL—
Sec., W. Fricker, Broad Street, Canterbury.
- CARDOFF—
J. G. Jones, Partridge Road, Roath, Cardiff.
- CARLISLE AND CUMBERLAND HORTICULTURAL—
Sec., John Mounsey, 14, Warwick Street, Carlisle.
- CARNATION AND PICOTEÉ UNION—
Sec., E. S. Dodwell, Stanley Road, Oxford.
- CASTLEROCK HORTICULTURAL—
Sec., W. Jackson, Castlerock, Co. Tyrone.
- CATERHAM HORTICULTURAL AND COTTAGE GARDENERS—
Hon. Sec., G. H. Rose, School House, Upper Caterham.
- CHEADLE HORTICULTURAL—
Hon. Sec., Edward D. Stone, The Depleach, Cheadle, near Manchester.
- CHELMSFORD HORTICULTURAL—
Sec., P. Edwards, Meadow House, Victoria Road, Chelmsford.
- CHELLENHAM AND COUNTY OF GLOUCESTER HORTICULTURAL—
Sec., W. H. Bridgewater, 57, Regent Street, Cheltenham.
- CHISWICK HORTICULTURAL—
President, Duke of Devonshire, K.G.; Sec., J. Fromow, Sutton Court Nursery, Chiswick.
- CHORLEY CHRYSANTHEMUM—
Hon. Secs., J. Sargent, Market Street, and W. Bromley, Cattle Market.
- CHRISTLETON ROSE—
Hon. Secs., S. Earlam, and T. Weaver, Christleton, Chester.
- CITY OF CORK CHRYSANTHEMUM—
Hon. Secs., D. S. Stoker, jun., Thornbury, Rochestown, Cork; W. B. Hartland, Temple Hill, Cork.
- CLAYCROSS HORTICULTURAL—
Sec., J. Stollard, Claycross, near Chesterfield.
- CLONMELL CHRYSANTHEMUM—
Hon. Sec., J. Phelan, Spring Gardens, Clonmell.
- CORBRIDGE HORTICULTURAL—
Sec., Jos. Thompson.
- COUNTY OF GLOUCESTER AND CHELTENHAM ROYAL HORTICULTURAL—
Sec., W. H. Bridgewater, 57, Regent Street, Cheltenham.
- COUPAR ANGUS HORTICULTURAL—
Sec., John M. Muir, Coupar Angus.
- CRAMLINGTON HORTICULTURAL—
Sec., R. Joyce.
- CREDITON HORTICULTURAL—
Hon. Sec., Sidney Kelland.
- CREWE HORTICULTURAL—
Sec., Wallace Lamb, Crewe.
- CROYDON HORTICULTURAL—
Hon. Sec., R. C. Roffey, Church Road, Croydon.
- CRYSTAL PALACE—
Horticultural Manager, W. G. Head, Crystal Palace, Sydenham, S.E.
- DARLSTON FLORAL AND HORTICULTURAL—
Hon. Secs., Joseph Yates and G. Willey, Darlaston.
- DARTFORD CHRYSANTHEMUM—
Sec., Robert Crane, 12, East Hill, Dartford.
- DAWLISH CHRYSANTHEMUM—
Hon. Sec., H. L. Friend, 3, Priory Terrace, Dawlish.
- DERBY CHRYSANTHEMUM—
Hon. Sec., F. Baneroft, Cobden Cottage, New Zealand, Derby.
- DEVIZES CHRYSANTHEMUM—
Hon. Sec., Mrs. G. Smith, Devizes; Manager, Mr. T. King, Devizes Castle.
- DEVON AND EXETER BOTANICAL, HORTICULTURAL AND NATURAL HISTORY—
Hon. Sec., G. D. Cann, 16, Queen Street, Exeter.
- DISS HORTICULTURAL—
Hon. Sec., Rev. F. Page Roberts, The Rectory, Scole, Norfolk.
- DONSET COUNTY HORTICULTURAL—
Hon. Sec., T. S. Biggs, Dorchester.
- DUNDEE HORTICULTURAL—
Sec., David P. Scott, National Bank of Scotland, Dundee.
- DUNKELD AND BIRNAM HORTICULTURAL—
Sec., Mr. James McIntosh, Dunkeld.
- DURHAM, NORTHUMBERLAND AND NEWCASTLE-ON-TYNE BOTANICAL AND HORTICULTURAL—
Sec., James Gillespie, A.C.A., Cross House Chambers, Westgate Road, Newcastle-on-Tyne.
- EALING, ACTON AND HANWELL HORTICULTURAL—
Hon. Sec., R. Dean, Ranelagh Road, Ealing.
- EARLEY DISTRICT COTTAGERS—
Sec., — Turtton, Maiden Erleigh, Reading.
- EASTBOURNE HORTICULTURAL—
Hon. Sec., T. H. Larkin, 5, Cornfield Road, Eastbourne.
- EAST GLOUCESTERSHIRE ROSE—
Hon. Secs., Rev. F. R. Burnside, Chipping Campden; and Rev. J. W. Clark, Moreton-in-Marsh.
- ECCLES AND PATRICKROFT—
EDINBURGH MARKET GARDENERS' ASSOCIATION—
President, — Gourlay, Musselburgh, Edinburgh.
- EDINBURGH CHRYSANTHEMUM—
Sec., R. Munro, 5, St. Andrew's Square, Edinburgh.
- EDINBURGH BOTANIC—
Hon. Sec., Dr. Macfarlane, 1, Wardie Avenue, Edinburgh, N.B.
- ELGIN TOWN AND COUNTY HORTICULTURAL ASSOCIATION—
Sec., James McPherson.
- ELTHAM ROSE AND HORTICULTURAL—
Hon. Sec., F. T. Bloxham, Eltham Court, Eltham, Kent.
- ESHER HORTICULTURAL—
Sec., Wm. Crump, Sandown House Gardens, Esher.
- FALKIRK SPRING SHOW—
Sec., Hugh Johnston, 4, Wooser Street, Falkirk.
- FAREHAM AND SOUTH HANTS HORTICULTURAL—
Sec., Harry Smith, Fareham.
- FARNHAM ROSE AND HORTICULTURAL—
Hon. Sec., J. H. Knight, Thumblands, Farnham, Surrey.
- FARNINGHAM ROSE AND HORTICULTURAL—
Hon. Secs., W. and J. Hodson, Farningham, Kent.
- FAVERSHAM CHRYSANTHEMUM ASSOCIATION—
Hon. Sec., C. Suddolph, Faversham.
- FERMOY HORTICULTURAL (CO. CORK)—
Hon. Sec., Robert Briscoe, Esq., Fermoy.
- FERNDALE HORTICULTURAL—
Sec., John Richards, Church Street, Ferndale.
- FRIMLEY, YORK TOWN, CAMBERLEY, AND SANDHURST HORTICULTURAL—
Hon. Sec., Major C. W. Valliamy, Royal Military College, Sandhurst.
- GATESHEAD HORTICULTURAL—
Sec., — Armstrong, 20, Wylam Street.
- GLAMORGANSHIRE HORTICULTURAL—
Sec., A. B. Bassett, Church Street, Cardiff.
- GLASGOW AND WEST OF SCOTLAND HORTICULTURAL—
Sec., Franc Gibb Dougall, 167, Canning Street, Glasgow.
- GOVAN HORTICULTURAL—
Sec., G. H. S. Buchanan, Water Street, Govan, Glasgow.
- GRANTHAM HORTICULTURAL—
Sec., O. Yeatman, High Street, Grantham.
- HADDO HOUSE HORTICULTURAL—
Sec., James Allan, Methlick.
- HARPENDEN HORTICULTURAL—
Hon. Sec., J. J. Willis, Harpenden.
- HASTINGS, ST. LEONARD'S, AND EAST SUSSEX HORTICULTURAL—
Hon. Sec., Stanley T. Weston, 3, Havelock Road, Hastings.
- HATCH HORTICULTURAL—
Hon. Sec., — Vile, Hatch, Beauchamp.
- HAVANT CHRYSANTHEMUM—
Hon. Sec., N. Fuller, The Gardens, Idsworth, Horndean, Hants.

- HAWICK HORTICULTURAL**—
Sec., A. Bell, Sillerbithall, Hawick, N.B.
- HAYLING ISLAND HORTICULTURAL**—
Sec., J. Hepper, Westfield, South Hayling.
- HAYDON BRIDGE HORTICULTURAL**—
Sec., J. H. Thompson.
- HENFIELD CHRYSANTHEMUM**—
Sec., M. Russell, Church Terrace, Henfield.
- HEREFORD AND WEST OF ENGLAND ROSE**—
Sec., H. Percy Bulmer, Credenhill Rectory Hereford.
- HIGHGATE, FINCHLEY, AND HORNSEY CHRYSANTHEMUM**—
Sec., H. Barnaby, Ivy Cottage, South Wood, Lane Highgate, N.
- HIGHGATE HORTICULTURAL**—
Sec., W. M. Burek, 14, North Road, Highgate.
- HITCHIN CHRYSANTHEMUM**—
Hon. Sec., E. B. Lindell, Beartons, Hitchin.
- HITCHIN ROSE**—
Hon. Secs., Rev. E. F. Carey, St. Ippolyt's, Hitchin; and Rev. F. H. Gall, Hope Cottage, Hitchin, Herts.
- HORTICULTURAL CLUB**—
President, John Lee, Esq.; Sec., Rev. H. H. D'Ombraim, Covent Garden Hotel, Southampton Street, Covent Garden, W.C.
- HUDDERSFIELD CHRYSANTHEMUM**—
Hon. Sec., John Bell, Luck Lane Marsh, Huddersfield.
- HULL AND EAST RIDING CHRYSANTHEMUM**—
Hon. Secs., Robert Collison and Edward Harland, 3, County Buildings, Hull.
- INVERNESS HORTICULTURAL**—
Sec., T. Findlay, Inverness.
- IPSWICH AND EAST OF ENGLAND HORTICULTURAL**—
Hon. Sec., Rev. H. A. Berners, Harkstead Rectory, Ipswich
- JEDBURGH HORTICULTURAL**—
Sec., Geo. McLean, 1, Abbey Place, Jedburgh, N.B.
- KINGSTON AND SURBITON CHRYSANTHEMUM**—
Hon. Sec., G. Woodgate, Warren House Gardebs, Kingston-on-Thames.
- KIRRIEMUR ROSE AND PANSY SHOW**—
Sec., John Brown.
- KELSO HORTICULTURAL**—
Sec., A. Brotherston, Sheddou Park Road, Kelso, N.B.
- LAMBETH AND SOUTHWARK AMATEUR CHRYSANTHEMUM**—
Hon. Sec., T. F. Davison, 9, Union Square, S.E.
- LEEDS GARDENERS' FRIENDLY**—
Hon. Sec., J. Sunley, Moortown, Leeds.
- LEEDS PANTON**—
Hon. Sec., Geo. Hemmings, Gr. to J. P. Bowring, Esq., Gledhow, Leeds.
- LEEDS CHRYSANTHEMUM**—
Hon. Sec., — Featherston, Kirkstall, Leeds.

THE AMARYLLIS.

PERHAPS I ought to notice the remarks on this plant at p. 818 of last year's volume by Mr. Culverwell. I recommended the use of 5-inch pots for weakly-constituted varieties. We have plenty of bulbs 5 inches in diameter. These we plant in 8-inch pots. What I was anxious to guard against was over-potting. Inexperienced cultivators are more apt to err on the side of over-potting than in the opposite direction.

Mr. Culverwell must not suppose that bulbs producing two spikes with four flowers on each are extra fine. Our largest bulbs of such noble varieties as *Empress of India* produce three spikes with five and six flowers on each. The largest number of flowers we have had open from one bulb at a time was seventeen, but this is unusual. Every year we can show some with fifteen flowers. I fancy only the more hardy varieties would thrive with the treatment recommended by Mr. Culverwell. The best varieties of the *Amaryllis* have been produced by hybridising *A. Leopoldii* and *A. pardina*. The progeny of these are too tender to be placed out-of-doors, and to be moved into frames when frost comes. On the other hand, there are some species, of which *A. vittata* may be taken as the type, which have produced much more hardy varieties. This species is well figured in the *Botanical Magazine*, and the plant there figured is probably the type form. It is there stated that "it rarely puts forth offsets from the root, but readily produces seeds, by which it is propagated without difficulty." From two to five flowers were stated to be produced on one scape. The figure was taken in 1791. Dean Herbert in 1837 describes *A. vittata* as producing from four to nine flowers. The largest number would probably be the produce of two scapes. From 1791 until the death of Dean Herbert, about fifty years later, the *Amaryllis* was well known in this country. Amongst others of the early varieties *A. Regina* held a leading place. This species was stated to have been grown in a Mr. Fairchild's garden at Hoxton in 1728. Miller, writing in the *Gardeners' Dictionary*, states that "this species, not being so hardy as some others, it must be placed in a warm stove, and if the pots are plunged into a hotbed of tanner's bark, the roots will thrive better, and the flowers will be strong." This species went under the name of the Mexican Lily. There is an excellent plate of it by Sydenham Edwards in *Bot. Mag.*, t. 453. Dean Herbert's work is well known, and those who would like to become acquainted with it will find a very complete record in the "*Amaryllidaceæ*," p. 142.

It is there stated that the first cross was made between the two species I have named by a Mr. Johnson, in Lancashire, in 1810, and by Herbert himself at Mitcham, in 1811, and again at Lighclere later. Herbert named it *Regio-vittatum*; and this hybrid is even now in existence—at least, I grew it until quite recently under the name of Johnsoni. Mr. Johnson thought this was a cross between *A. vittata* and *Sprekelia formosissima*. A cross between these comparatively hardy species would produce a progeny that might be hardy in our climate; but

Herbert doubted whether a cross had ever been made with this Jacobean Lily and the *Hippeastrum*. He says no instance had ever come to his knowledge of it bearing seeds in this country. As far as my own knowledge extends, I have never known it to cross with *Hippeastrum*. Herbert tried it with *Hippeastrum* and *Zephyranthus*, but failed. The Jacobean Lily produces pollen abundantly, and it is just possible that others may have been successful with it; in fact, it is distinctly stated that *H. spathaceum* (*Bot. Mag.*, t. 2315) is a *Sprekelia* cross and the coloured plate would certainly lead one to believe that it was a cross from the Jacobean Lily.

H. spathaceum hyb. was flowered by Mr. Joseph Knight, of the Exotic Nursery, Chelsea, in 1822, who stated that they received the bulb from Mr. E. Bearpark, a gardener in Cheshire, who gave particular attention to the culture of this class of plants. Mr. Bearpark's letter to Mr. Knight is worth quoting in part. He says, "that in 1814 he impregnated *Amaryllis vittata* with the pollen of *A. Regina*; the seed produced was sown in 1815, and part of the progeny flowered in 1818. The early flowers were most of them stripped of their pollen, and impregnated with that of *A. formosissima*, and amongst the produce was one different from the rest, bearing its flowers erect, and blooming one at a time in succession." This is evidently the plant figured, although it has two flowers open on the scape. It does seem to me that many of the hybrids raised in those days, and later on, were from the hardy Cape species; but as garden plants they cannot for a moment be compared with the beautiful forms of the present day; in fact, thirteen of Dean Herbert's crosses were either from *H. vittatum* or *H. Johnsoni*. Doubtless many of the beautiful varieties raised at that time have perished; but many of them may yet remain; and by a process of what may be termed natural selection the more tender varieties would disappear, while the hardier would remain to be the parents of those yet to be found in old gardens.

We read of the *Amaryllis* growing freely out-of-doors in some districts; and it is certainly very desirable that such hardy forms should be improved by seeding from other hardy varieties. The Jacobean and *Belladonna* Lilies, for instance, if they really can be crossed with the hardy types of the true *Hippeastrum*, would produce valuable plants for sheltered positions in our hardy flower gardens. Mr. Kelway has, I believe, been conducting experiments with the hardy forms of *Hippeastrum*, and can doubtless give valuable information. Mr. Frank Miles, writing to a contemporary quite recently, states that *A. Ackermanni pulcherrima* is grown quite in the open at Calke Abbey, in Derbyshire, where there is a border 200 feet long of it, and in winter it is only covered with Bracken. This variety is so slow of increase, that I cannot conceive of any one having 200 plants of it, let alone a border out-of-doors 200 feet long. I cannot get any increase from a healthy bulb. I fancy there must be some mistake, and that the border is made up of the Jacobean Lily, which is of the same colour. Mr. Miles' statement can easily be verified if it is correct.

Let it be proven that *A. Ackermanni pulcherrima* will grow in borders out-of-doors, many other supposed tender varieties might also grow with it. Mr. Miles also doubts if the Jacobean Lily has ever been crossed with *Hippeastrum*. Herbert also doubted it; and I must say that, after a determined effort to cross it with *Hippeastrum*, I gave it up. There is yet a large field for the hybridiser in this interesting genus. Suppose *Ackermanni pulcherrima* to be quite hardy, with the protection of Bracken, we have a valuable parent, as it can be crossed with other species, though not very freely. The beautiful varieties *Chelsoni*, *Brilliant*, &c., were obtained in Messrs. Veitch's nursery at Chelsea by crossing it with *A. pardina*. The *Amaryllis* is now so universally cultivated in the best gardens, that it is not too much to suppose, some one may have raised very interesting hybrids; and I am sure any information as to hardiness, or new crosses would be most welcome.

I may add that our largest bulb measured, after the outer layers were cleared off and the bulbs potted, 17 inches, and the second size, 15 inches in girth. *J. Douglas.*

THE WEATHER.

Accumulated temperature indicates the combined amount and duration of the excess or defect of temperature above or below 32° F. for the period named, and is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

THE PAST WEEK.

The following summary record of the weather for the week ending Jan. 9, is furnished from the Meteorological Office:—

"The weather was in an unsettled and rainy condition during the earlier part of the period, but subsequently became fine and unusually warm for the time of year generally, although, in many parts of England thick local fogs were experienced. The rainfall which occurred over Ireland on the 3rd and 4th was very heavy.

"The temperature has been above the mean in all

districts, the excess ranging from 3° in 'England, S.W.' and the 'Channel Islands,' to 5° in Ireland and some parts of England, to 6° in 'Scotland, W.,' and 7° in 'Scotland, E.' The absolute maxima, which were recorded either on the 8th or 9th, were, in many places, abnormally high for the season. In Ireland and over eastern and central England the thermometer rose to 59°, and in 'England, N.E.' (at Durham) to 63°. In 'England, S.,' and the 'Channel Islands,' however (where the weather was misty or foggy), the highest reading was 53°. The lowest of the minima were registered as the period commenced, when the temperature fell to between 26° and 31° generally, and to 41° in the 'Channel Islands.'

"The rainfall has been more than the mean in Ireland, and about equal to it in 'Scotland, N.' but in all other districts it has been less than the normal. At many of the English stations the fogs were sufficient to produce measurable amounts of water in the gauge.

"Bright sunshine has been very little prevalent, the percentage of the possible amount of duration ranging from 7 to 15 in Scotland, and from 12 to 29 in Ireland and England."

MEAN TEMPERATURE OBSERVED AT CHISWICK DURING THE WEEK ENDING JAN. 21. (AVERAGE OF FORTY-FOUR YEARS.)

" 16	36°.	" 20	37°.4
" 17	36°.8	" 21	37°.5
" 18	36°.9	Mean for the week ...	37°.0

ENQUIRIES.

"He that questioneth much shall learn much."—BACON.

Would you kindly inform me—1. What are the best twelve dessert late-keeping Apples to grow in New Zealand, to stand the voyage, and send to the London market? 2. The best twelve late cooking Apples for the same purpose as above? 3. Three of the largest and best baking Pears? I have a friend who is going out to New Zealand, and intends to grow fruit. He would like to know the best sorts suitable for growing out there for the London market. *J. N. Lowless.* [We are not able to give the information. The following sorts are in the greatest demand in the London market:—Kewick Codling, Lord Suffield, Hawthornden, Dr. Harvey, Stone's Pippin, Northern Greening, Alfriston, Peasgood's Nonsuch, Golden Noble, Gloria Mundi, Beauty of Kent, Wellington, Blenheim, Golden Russet, Duchess of Gloucester, Nonsuch, King of the Pippins, Cox's Orange, Ribston, and Sturmer. Ed.]

NOTICES TO CORRESPONDENTS.

INTELLIGENT READERS, do PLEASE NOTE that letters relating to ADVERTISEMENTS, or to the supply of the Paper, should be addressed to the PUBLISHER, and that all communications intended for publication, as well as specimens and plants for naming, should be addressed to the EDITOR. Such communications should be written on one side only of the paper, and sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

BRUGMANSIA SCAVEOLENS: *F.* This plant was described by Loudon in *Hortus Britannicus*, p. 60. It is there said to be an inmate of the bark, or moist stove.

CORRECTION.—In "Hardy Fruit Garden," last week, p. 15, I omitted to give $\frac{1}{2}$ lb. of soft-soap as one of the ingredients of petroleum emulsion. *A. Ward.*

DRYING FLOWERS *K. A. L.* Use a saturated solution of sulphurous (not sulphuric) acid, which you may procure at the chemist's.

ELEAGONUS EDULIS: *G. H. M.* We do not know precisely what you mean, but all the species are hardy, not particular as to soil, and if you like you may eat the berries, but you will hardly care to repeat the process.

JUNIPERUS SABINA: *Juniperus.* Yes, decidedly, to both.

NAMES OF FRUIT: *J. N.* Blenheim Orange.—*Clark Brothers & Co.* Apple, Yorkshire Greening.—*Elizabeth C.* 1, Golden Noble; 2, not recognised; 3, Court Pendu-Plat; 4, Sturmer; 5, Golden Pearmain; 6, Court of Wick.—*E. H.* Beurré Rance.

NAMES OF PLANTS: *H. W. D.* *Linum trigynum*, otherwise *Reinwardtia trigyna*.—*Crocker & Sons.* *Arbutus*; perhaps *A. procera*, or else a form of *A. Andrachne*. Leaves insufficient to enable us to determine more definitely.—*S. A. B.* *Brassia verrucosa*.—*E. C.* *Vanda concolor*.—*X. Y. Z.* *Tecoma capensis*.—*J. L. H.* *Epidendrum ciliare*, *J. McP.* *Odontoglossum hebraicum*; the *Cœlogyne* is the Chatsworth variety.—*J. H.* 1, *Begonia* (we do not name these); 2, *Davallia canariense*; 3, *Polystichum angulare*; 4, *Aspidium glabellum*; 5, *Selaginella viticulosa*; 6, *Davallia bullata*.—*J. F. P.* *Clematis indivisa*; 1, *Adiantum Pacottii*; 2, *A. cuneatum* var.; 3, *A. Sancta-Catherinae*; 4, *Pteris cretica*; 5, *Adiantum cuneatum* var.; 6, *A. hispidulum*.

NEW ZEALAND: *E. Spooner.* The article kindly sent was published in our columns September 10 last. The other will appear shortly.

VEGETABLE PALEONTOLOGY: *A. B.* The most complete book is that of Schimper, but it is costly. Unger's *Genera Plant. Fossil.*, Vienna, 1850, is still useful, and so is Brongniart's *Classification et Descript. des Veg. Fossiles*, 1822. There are, of course, very numerous separate memoirs by Mr. Carruthers, Mr. Starkie Gardiner, Prof. Williamson, and others. Application at the Geological Society would secure you full information.

CATALOGUES RECEIVED.

- WM. PAUL & SON, Paul's Nurseries, Waltham Cross—Seeds and Sundries.

A Sterling Novelty for 1888. "FERTILIZING MOSS." Intelligent Plant Growers will find this medium for Plant Culture to be eminently useful. It suits both Soft and Hard-wooded Plants, Ferns, ORCHIDS, and Succulents. (Of a totally different character to the "Damesnil" Fertilized Moss.) This is the quality so successfully used by Mr. Roberts at Gunnersbury for Bourardias and Gloxinias; see Gardeners' Chronicle, December 31 and November 12, 1887. Send for full particulars, testimonials, and prices to the Sole Manufacturers, W. WOOD & SON, Wood Green, LONDON, N. ESTABLISHED 1850.

LINDLEY'S MEDICAL and ECONOMIC BOTANY. With numerous Illustrations. 8vo, 10th. Price 5s.

LINDLEY'S DESCRIPTIVE BOTANY. For Self-Instruction and the Use of Schools. Price 1s. sewed. London: BRADBURY, AGNEW AND CO., 9, Bouverie Street, E.C.

THE GARDENERS' CHRONICLE

(Established 1841)

CONTAINS ARTICLES ON ALL DEPARTMENTS OF

GARDENING,

NOTICES OF ALL HORTICULTURAL MATTERS OF CURRENT INTEREST,
 REPORTS OF EXHIBITIONS, REVIEWS OF BOOKS, and
 HOME, COLONIAL, and FOREIGN CORRESPONDENCE.

Original Illustrations by W. H. FITCH, F.L.S., W. G. SMITH, F.L.S., W. J. WELCH, and Others.

Among the Contributors to recent Volumes the following, out of many hundreds,
 may be named:—

ALPINE PLANTS:—

BACKHOUSE, J.
 BALL, J., F.R.S.
 CHURCHILL, G. C., Clifton, Bristol.
 CORREVON, H., Geneva.
 DEWAR, D., Kew.
 DOD, Rev. C. W.
 JENKINS, E., Fother.

AMATEUR GARDENING:—

BADGER, E. W.
 BOYLE, Hon. Mrs. E. V. B.
 "S. BRIGID."
 BRIGHT, the late H. A. ("Notes
 from a Lancashire Garden").
 CLARKE, Col. Trevor.
 EWBANK, Rev. H., Ryde.
 LOWNE, B. T.
 OWEN, Miss, Knockmullen.
 PHILBRICK, Q.C.
 THOMSON, W.
 WEIR, HARRISON.

ARBORETUM:—

BARRON, W., Borrowash.
 LAVALLEE, Alphonse, the late.
 NICHOLSON, G., Curator, Royal Gar-
 dens, Kew.
 SARGENT, Prof., Boston, U.S.A.
 WEBSTER, A. D.
 YOUNG, Maurice.

BEE-KEEPING:—

CHITTY, W.
 ROBINSON, J. F.

CHEMISTRY:—

CHURCH, Prof., Kew.
 DEHERAIN, Prof., Paris.
 DYER, Bernard.
 GILBERT, Prof., Rothamsted.
 LAWES, Sir J., Rothamsted.
 WASHINGTON, R., Rothamsted.
 WILLIS, J. J.

DISEASES OF PLANTS:—

ARTHUR, Prof., New York.
 BASTIAN, Dr. Charlton, F.R.S.
 BELJERINCK, Prof., Wageningen.
 BERKELEY, Rev. M. J., F.R.S.
 COBBOLD, T. S., F.R.S., the late.
 COOKE, Dr. M. C.
 MURRAY, J., British Museum.
 PAGET, Sir James, F.R.S.
 PHILLIPS, W.
 PLOWRIGHT, C. B., (Fungi).
 SMITH, W. G.
 SORAUER, Prof., Proskau.
 WARD, Prof. Marshall, School of
 Forestry.

FERNS:—

BAKER, J. G., Royal Gardens, Kew.
 DRUERY, C.
 HEMSLEY, A.
 MOORE, T., Botanic Gardens, Chelsea.

FLORISTS' FLOWERS:—

DEAN, R., Ealing.
 DODWELL, E. S., Oxford.
 D'OMBRAIN, Rev. H. H.
 DOUGLAS, J., Ilford.
 DOWNIE, J., Edinburgh.
 HORNER, Rev. F. D.
 MOLYNEUX, E.
 PAUL, O., Paisley.
 TURNER, C., the late.

FOREIGN CORRESPONDENCE:—

ANDRÉ, E., Paris.
 ANTOINE, F., the late, Vienna.
 BENNETT, H., M.D., Mentone.
 BERGMAN, E., Ferrières.
 BONAVIA, C., Lucknow.
 CARUEL, Prof., Florence.

By Royal Letters Patent.—Carbon Cones.

LETHORION (VAPOUR CONE).

For the distribution of certain principles in a state of vapour, in Greenhouses and Conservatories, whereby their active properties are most closely brought into direct and intimate contact with vegetable productions, for the purpose of DESTROYING PARASITIC LIFE with a certainty hitherto unachieved, and without hurt or prejudice to the most delicate and fragile organization of plant life. The old system of fumigating with cloth or paper is now quite unnecessary.

Cones, cub. feet.	PRICES.	Per case.
No. 0, 50 (for Window Cases and Small Frames from 10 cubic feet)	5d.	Two doz. 10s. 6d.
" 1, 100 (for Frames, &c.)	9d.	15s.
" 2, 500 (for Small "Lean-to's," &c.)	1s. 3d.	13s. 6d.
" 3, 1000 (for general use in Larger Greenhouses)	2s.	Half doz. 11s.

Directions for use with each Cone.

JAMES VEITCH & SONS, Royal Exotic Nursery, CHELSEA, LONDON, S.W.

VEGETABLE AND FLOWER SEEDS DIRECT FROM THE FIELDS!

CANNELL'S NATURAL

NATURE makes it an IMPERATIVE FACT that KENT possesses a more favourable CLIMATE and SOIL than any other county in England (perhaps even in Europe) for the production and RIPENING of Seeds, also in COLOURING, BRIGHTNESS, PLUMPNESS—the Force of Life or Germinating Power stronger to withstand unfavourable weather, and far MORE PROLIFIC. Coming from a calcareous subsoil, the thorough change (SO ESSENTIAL) makes the yield of our seeds marvellously rich and productive. Further, we are determined that the purchaser shall have the CHOICE and ADVANTAGE of Seeds DIRECT from the ACTUAL GROWERS, and thus avoid the risk and deterioration where seeds are bought

CANNELL'S ADVANTAGES.

and sold half-a-dozen times between the SAVERS to the SOWERS. Our Illustrated Catalogue for the Garden contains a vast amount of invaluable information on high-class culture and gardening, and enables amateurs to be supplied with the BEST of all WANTS FROM THE GROWERS. Replete with 550 Engravings, Two large Views of our SEED FARM, The TWO HARD WORKERS, and Three magnificent COLOURED PLATES of New and Improved Plants and New Invaluable Vegetables—so important to successful prizetakers. The whole are really a gift to the nation.

Post-free to Previous, Present, and Coming Customers.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION. At a General Meeting of the Subscribers to this Institution, held on FRIDAY, the 13th January, 1888, for the purpose of making an Addition to the List of Pensioners, it was resolved "That in consequence of Four Vacancies having occurred in the List of Pensioners since the voting papers were issued, after the Five Pensioners for whom the Election is called have been Elected the Four next highest on the poll shall be declared Elected." CANDIDATES.

Table with columns: Votes, Name, Age. Lists names like MATILDA CHARLTON, STEPHEN EVANS, JAMES EWING, etc., with corresponding votes and ages.

The Meeting then declared Thomas M. Wall, Matilda Charlton, Charles Pappworth, James Ewing, William H. Head, Elizabeth Horton, Henry Moxham, Francis Fuller, and Mary Nelson duly elected Pensioners of this Institution, from 25th December, 1887. E. ROGER CUTLER, Secretary. 50, Parliament Street, S.W., January 16, 1888.

GARDENERS' ORPHAN FUND. Donations and Subscriptions promised or sent.

ELEVENTH LIST. Table with columns: Donations, Subscriptions. Lists names like Temple, Mrs., Leyswood, Tunbridge Wells, Tucker, R., Faringdon, Berks, etc., with donation amounts.

CANNELL'S SEEDS PERFECT ONLY—DIRECT FROM SWANLEY—KENT. THE GREAT CONTEST!

PRIMULAS.—Hitherto, through not competing, our exhibits did not receive that comment it was thought they deserved; consequently we entered for competition at the Royal Aquarium National Primula Show for the best collection, staging 20 lovely and distinct varieties, side by side with the oldest, largest, and the most expert growers in England, and the greatest miscellaneous exhibitors, and the result was

THE FIRST PRIZE.

None of the others bore even the slightest comparison to ours. Above and beyond the highest award we were presented with an EXTRAORDINARY SPECIAL CERTIFICATE BEARING THE FOLLOWING WORDS:—

"We hereby certify that this Certificate has been awarded to H. CANNELL & SONS for an excellent representative collection of Primulas of high-class quality at the Exhibition of the National Society held January 11th, 1888.

"JUDGES (Signed, RICH'D. DEAN, Signed, GEO. GORDON."

Together with Two First-class Certificates, which clearly demonstrates beyond all dispute, and is certainly the most conclusive proof of the superiority of our varieties over all others. The day previously, at the Royal Horticultural Society, the same plants were unanimously granted the high distinction of a Silver-gilt Medal by the Floral Committee, and a First-class Certificate. In addition, the oldest and greatest experts pronounced the collection THE BEST AND MOST COMPLETE EVER EXHIBITED.

- CANNELL'S WHITE PERFECTION (First-class Certificate), Seeds, 2s. 6d. per packet.
- CANNELL'S BLUE (First-class Certificate), 4s. per packet.
- CANNELL'S SWANLEY RED (First-class Certificate), 2s. 6d. per packet.
- CANNELL'S IMPROVEMENT (First-class Certificate), 4s. per packet.
- CANNELL'S PURPLE (First-class Certificate), 2s. 6d. per packet.
- CANNELL'S PRINCE OF WALES (First-class Certificate), 2s. 6d. per packet.
- CANNELL'S SWANLEY GIANT, 4s. per packet.
- CANNELL'S SWANLEY WHITE, 2s. 6d. per packet.
- CANNELL'S DOUBLE, 5s. per packet.
- QUEEN OF WHITES (First-class Certificate), 2s. 6d. per packet.
- THE QUEEN (First-class Certificate), 2s. 6d. per packet.
- BRAID'S SEEDLING (First-class Certificate), 2s. 6d. per packet.

(IMPORTER of PLANTS and BULBS),

68, NORTH 38TH STREET, PHILADELPHIA, U.S.A.

THE EARLIEST OF ALL POTATOS,

"SHARPE'S VICTOR."

Sharpe's Victor is a seedling raised from the Alma Kidney and the old early short top round Potato. It is earlier than any present variety, and having a very short tap it is especially suitable for frame cultivation. Its precocity is such that it can be had fit for the table in eight weeks or less from the time of planting, and there is no difficulty in securing new Potatoes for the table every day in the year. Victor is a flat, not roundish oval in shape, with a beautiful clear skin and extremely shallow eyes, being one of the handsomest as well as the heaviest cropper of any variety adapted for frame work, or for a first early crop outdoors. It is dry and mealy when cooked, and the flavour and the quality of the flesh are superior to nearly every other variety at present in use.

Several seasons' trials have fully confirmed all that has been said in favour of the Victor Potato. It is proved to be the earliest, most prolific, and best flavoured of all the early Potatoes; and for Pot Culture is unrivalled.

Price, 6d. per Pound. 7 lb. delivered free. VICTOR is very scarce this season, and Early Orders are respectfully requested.

CHARLES SHARPE & CO., SLEAFORD.

All Flower and Vegetable Seeds are supplied Post-free, and arrive within 10 days after receipt of order.

A 92-Page

CATALOGUE,

embellished with

109 ENGRAVINGS,

(many of which, like the flowers they illustrate, are original), consisting exclusively of

FLOWER SEEDS.

I have much pleasure in announcing that my New CATALOGUE of Flower Seeds is now ready, and has been Posted to all Customers, who will doubtless welcome it as a valuable Catalogue for reference, and to whom, I am sure, it will prove especially instructive and attractive. Considering that its pages are devoted to Flower Seeds only, it is perhaps not too much to claim, that it is the LARGEST CATALOGUE of these ever published, and includes in its varied columns very many species and varieties, which can be procured from Tottenham only; and while desirous to introduce a large amount of stuff not generally known, I have—as is my wont—had due and proper regard to the fact, that as a rule buyers do not care for specialties unless they are distinct and effective. All the novelties and varieties appearing in this Catalogue claim such a distinction.

Copies may be had Gratis and Post-free upon application.

Kindly mention this Paper when writing for Catalogue.

B.S. WILLIAMS' PRIZE FLOWER SEEDS,

The Finest in Cultivation, Post-free.

WILLIAMS' PRIZE STRAIN OF CINERARIA
 (extra choice, mixed).
 Per Packet, 1s. 6d. and 2s. 6d.
 A superb strain of very dwarf branching habit and strong constitution, containing a great variety of colours.

WILLIAMS' PRIZE COCKSCOMB.
 THE FINEST IN CULTIVATION.
 Has gained numerous First Prizes.
 Per Packet, 2s. 6d.

WILLIAMS' CYCLAMEN GIGANTEUM, mixed, containing four varieties.
 Per Packet, 2s. 6d.
CYCLAMEN PERSICUM, mixed.
 Per Packet, 1s. 6d. and 2s. 6d.
 The finest strain in cultivation. For varieties of Cyclamen in separate colours, see Illustrated Seed Catalogue.

WILLIAMS' PRIZE STRAIN OF GLOXINIA, CHOICE MIXED.
 Per Packet, 1s. 6d. and 2s. 6d.
 This produces immense flowers of the most brilliant and varied colours, both of the erect and drooping varieties.

WILLIAMS' PANSY, Show Varieties. FINEST MIXED.
 Per Packet, 1s. and 2s. 6d.
PANSY, Fancy Varieties. FINEST MIXED.
 Per Packet, 1s. and 2s. 6d.
 Seed Saved from Prize Flowers.

WILLIAMS' POLYANTHUS, GOLD LACED.
 Per Packet, 1s.
VERY SUPERIOR STRAIN.
 Has taken numerous First Prizes.

WILLIAMS' PRIMULA SINENSIS FIMBRIATA, mixed packets, containing six varieties.
 Per Packet, 1s. 6d. and 2s. 6d.
 This superb strain has stood the test for 30 years, and never fails to take 1st-prizes wherever exhibited. For new Primulas and superb strain of Primula, see Illustrated Seed Catalogue.

TUBERS.*

"WHAT causes determine the position and growth of tubers?" This is the question stated by Dr. Vöchting, now of Tubingen, late of Basle; and it will be conceded by all who examine his attack on this problem that, whether he has brought it within the bounds of solution or not, he has, at any rate, obtained much instructive information about it, and succeeded admirably in conveying the results to his readers.

Tubers are usually regarded as of two chief kinds—stem-tubers and root-tubers. Only the former are dealt with here, and these again fall into two physiological classes; for while some are perennial structures (e.g., Begonia, Cyclamen, Tropæolum), others are developed annually in the autumn, &c., to sprout and pass away the following spring (e.g., Potato, Helianthus tuberosus, Ullucus tuberosa).

The perennial tubers behave differently from the annual ones in several respects; they form at the apical end the leaf-shoot, and at the base (or all over the lower part) roots, the tissue of the tuber acting as a collar or "root-stock" to the plant. This "root-stock" gives up part of its reserve materials to the growing shoot in the spring, but the cells remain living and again fill with reserves in the summer.

The annual tubers referred to produce leaf-shoots, but as a rule no roots; and the parent tuber thus simply brings into existence the young new plant, and then dies off.

In the present work Dr. Vöchting deals with the tubers of the Potato at great length, and with those of Ullucus tuberosa, Helianthus tuberosus, and Begonia more shortly. First we have experiments proving that the influence of the surrounding circumstances profoundly affects the mode of germination (sprouting) of the Potato tuber. If

* On the Development of Tubers. By Dr. H. Vöchting. (Bibliotheca Botanica, II. 4.) Cassel, 1887.

no water is added, the tubers in the light produce short, thick, green sprouts; those in the dark form long, thin, pale outgrowths. Moreover, those in the dark begin to sprout much earlier, and carry on the processes more rapidly. Light alone, then, has a checking action on the growth.

If tubers are allowed to sprout under such circumstances that water is conveyed to the young roots, which develop from the shoots (not from the tubers themselves), the relative behaviour is the same, only the shoots produced from those in the light do not remain short and fat, but the internodes subsequently formed develop, and richly branched leafy shoots are produced. In other words, although the light checks the elongation of the lower internodes, it has no such pronounced action on the later ones if plenty of water be supplied for their growth. Dr. Vöchting takes advantage of these and other properties in devising experiments in what may be called the vivisection of the Potato.

For instance, when he allows the tuber to sprout in the dark, with a minimum supply of water, the reserve substances from the parent tuber collect gradually in the apical and axillary buds of the shoot, and simply form young tubers; in other words, by preventing the tuber from growing out normally, it re-arranges its reserves in a series of young tubers and so delays the growth for the present year, ready to renew it twelve months later. In other cases, the author succeeded in making the tuber, planted half in and half out of the soil, act as a root-stock; tubers were developed on stolons from the base of the planted tuber, the leafy shoots from its exposed apex. The interesting point is that the plastic substances from the leaves, &c., must here have passed through the planted tuber. In other cases the tubers were compelled to develop in the leafy parts exposed to the light and air. By carefully cutting off and removing the tuber and stolons below the surface of the earth, and seeing that only roots were allowed to enter the soil, the author succeeded in keeping the whole of the tuber-forming substances above ground. The result was that the young Potatoes developed in the axils of the ordinary leaves—in fact, the reserve materials from the leaves passed into the axillary buds, which grew larger and larger, and stored them up, thus becoming converted into Potatoes. Dr. Vöchting also develops Potatoes from cuttings, and comes to the conclusion that it is a matter of importance which end of the cutting is planted; he finds that internal causes determine that roots and tubers shall normally be developed at the basal ends, the leafy parts at the apices; nevertheless, experiment shows that it is possible to so arrange matters that the influence of the environment is stronger than the influence of the internal (and inherited) disposition, and he can so arrange matters that tubers spring from the apex. It would require a chapter to itself to enter into the discussion which rages about this conflict between the influence of the present environment and the so-called "internal disposition" of plants, and we must refer readers to the original for further details.

One of the most interesting experiments in the book shows that although under normal conditions the young tubers fill with starch as they grow, it is possible to have them first developing and growing larger and larger by the division of their cells, and then filling with reserve materials later on—in fact, two physiological processes which normally go on simultaneously, were here separated in time.

We must now conclude this notice, however, simply remarking that although enough has been stated to illustrate Dr. Vöchting's chief results, we have by no means given a full abstract of his ingenious experiments.

That the author is doing good work in experimenting thus on the influence of the various factors of the present environment on the working of that complex something which has resulted from the inter-action of past environments, and which is called the organisation of the plant, will, no doubt, be willingly conceded; it is true, we cannot agree

with all his theoretical conclusions, but at the same time we feel somewhat strongly that his working hypotheses are likely to lead to better views of some very difficult subjects. *Marshall Ward.*

ADIANTUM CAPILLUS VENERIS VAR. IMBRICATA.

This pretty form of the true Maidenhair Fern (fig. 11) was raised recently by Mr. G. Masters, the gardener to Colonel C. Lee, High Lee, Knutsford, Cheshire. It was described by Mr. Moore, the description having been published since his decease, see *Gardeners' Chronicle*, April 23, 1887, p. 547. The fronds are about 1 foot in length, rather broader at the base than those of the typical *A. Capillus-veneris*, and have a drooping habit, which is in a large degree due to the greater size of the pinnae. The pinnae are larger than those of the parent, and the extreme edges, instead of being plain and entire, are much divided, some of the divisions running up to half the length of the pinnae, whilst the pinna is broadened out at its extremity, and as they are closely set together on the frond, the whole reminds one at first sight very much of a small frond of *A. Farleyense*. This capital sport can be grown cool, in fact to get it to show its true character it must be grown in quite a greenhouse temperature. Here the fronds will be of a deep green colour, and the plants remain vigorous and healthy, which would not be the case if placed in a hothouse. It is a variety which will soon become a general favourite in gardens.

NEW OR NOTEWORTHY PLANTS.

DENDROBIUM STREBLOCERAS (*Rehb. f.*) ROSSIANUM, *n. var.**

A NEW variety of the curious *Dendrobium strebloceras*, introduced by Messrs. Linden (Horticulture Internationale, Brussels), has just flowered. Mons. Lucien Linden expressed the ardent desire that this excellent variety might be dedicated to M. le Commandeur H. T. Ross, of Florence, *Le grand amateur Anglais* of Castagnolo, Lastra a Signa. The plant does not appear to differ in any manner from the typical *Dendrobium strebloceras*. It had lurked amid the stores of that species for years, when it suddenly surprised Messrs. Linden by its unexpected flowers of a whitish colour. After having been a few days in my room, the lip and the tips of the sepals turned a light yellow colour; the neatly twisted petals, however, were light greenish from the beginning. *H. G. Rehb. f.*

PAPHINIA CRISTATA (*Lindl.*) MODIGLIANIANA, *n. var.*

A new introduction from Brazil, kindly sent me by Messrs. Linden, of Brussels (Horticulture Internationale), who shortly before had the most distinct *Paphinia Lindeni* in flower. It has all the most minute characters of the old types, but its flowers are almost whitish, and this is quite extraordinary in such Orchids as have claret or port-wine coloured flowers. Monsieur Lucien Linden proposed its being named in honour of Cavaliere Ludovic Modigliani, of Florence. The old town on both sides of the Arno appears likely to become the unrivalled nucleus of Italian orchidophilia. No doubt, the Commendatore H. T. Ross is to be regarded as the *causa movens* of a success in the wonderful garden of Europe, the possibility of which was firmly denied not very long ago. *H. G. Rehb. f.*

ONCIDIUM CARYORHAPIS, *n. sp.†*

This was kindly sent me by Mr. F. Sander, who imported it from St. Catherine, in Brazil. The

* *Dendrobium strebloceras* (*Rehb. f.*) *Rossianum*, *n. var.*—Floribus albis; tepalis viridulis; labello sepalisque demum flavescensibus. Col. exc. Linden. *H. G. Rehb. f.*
† *Oncidium caryorhapis*, *n. sp.*—Aff. *Oncidium cornigerum*, *Lindl.*; inflorescentia virgulata, brachyclada, apice racemosa; sepalis latissimis, sepalis impari transverso; sepalis conato

pseudobulbis are tereti-fusiform, dark green, 3 to 4 inches long. Leaves cuneate, oblong-lanceolate, acute, very dark green, glossy above, 6 to 7 inches long, by 1½ inch wide. The inflorescence is virgulate. The main rachis is brown, with numerous dark green spots. The pedicels are very short, densely three to five-flowered, the top, of course, being racemose. The whole makes a compact mass. Sepals and petals light sulphur-yellow, their disc being nearly covered with dark brown spots. Those form one mass, with extended external processes in the upper sepal and the petals, whereas they are partly separate and biseriate in the connate body. All these organs are very broad. Side-lacinia of the lip linear, lobed at the top, erect. Unguis covered with tumours. Anterior blade reniform, emarginate, very large. The tumours are nearly the same as those of *Oncidium cornigerum*, but they extend into a contiguous mass, full of rough processes at the base of the anterior blade. This is for me the leading point. Let me add, that the genus *Oncidium cornigerum* has the lateral sepals much slit. Column much like that of the above-named species, but the wings are a little lobed at the top, and tabula very strong. *H. G. Rehb. f.*

AERANTHUS GRANDIDIERIANUS, *Rehb. f.**

This plant was discovered on the great Comoro Island by Mr. Léon Humbolt, who desired it named in honour of M. Grandidier, the celebrated traveller in Madagascar. It was described by me in the *Flora*, vol. lxxviii., 1885, July 11, p. 381. I feel very pleased to have it now at hand in a fresh state, Messrs F. Sander & Co. having just flowered it. It is a caulescent species, most probably never producing a tall stem. The leaves are cuneate-oblong, unequally blunt, bilobed, attaining 3 inches in length by 1 in width. The peduncle is few-flowered, and I suspect there are never more than two flowers developed at one time. Well grown flowers reach the dimensions of those of *Angræcum Cbailluanum*. The whole flower is yellowish with a greenish hue, and the bases of the sepals and petals are quite green, in those which I have at hand. Sepals ligulate, the lateral ones falcate; tepals spatulate ligulate acute; lip's blade triangular, blunt edged; spurs with a very wide compressed mouth, that passes suddenly into a long filiform acute spur, five times as long as the blade of the lip. It would appear to be variable, as I saw it curved, and also rolled round at the base in a circinate manner. The column, anther, and pollinaria are quite those of *Aeranthus*. It is a very interesting plant, nice for students of Orchids, but not an ornamental thing for exhibition orchidists. *H. G. Rehb. f.*

MOHODES PARDINUM VAR. UNICOLOR.

An inflorescence of this handsome and apparently very rare Orchid has just been sent to name, its flowers being of a uniform bright canary-yellow—precisely the form figured in the *Botanical Magazine*, t. 3879. Bateman, who figured the species in his *Orchidaceæ of Mexico and Guatemala*, t. 14, remarks that the plant is a native of Oaxaca, where it was originally discovered by Baron Karwinsky. It formed a part of a most extensive collection of vegetable treasures which that distinguished traveller had assembled during his researches in New Spain, and which he attempted to bring with him on his return to Europe. Unfortunately, however, the vessel in which he sailed was wrecked on one of the West Indian Islands, and thus by far the greater portion

apice bidentato; labelli laciniis lateralibus curvatis linearibus apice retuso minute lobulatis, ungue basico cuneato, ungue mediano callis tecto, lacinia antica reniformi biloba transversa, callo maximo, longitudinaliter bifido erecto, crasso, gyroso sulcato tuberculoso, callo altero anteposito subaequali non bifido, in lacinie mediane basin transeunte; columnae alis linearibus apice lobulosis.—St. Catharina, imp. exc. F. Sander. *H. G. Rehb. f.*

* *Aeranthus Grandidierianus*, *Rehb. f.*—Caulescens, foliis cuneato-oblongis apice inaequaliter bilobis; racemo uni-bi (tunc tri-) floro (tunc vix synantho); bracteis triangularibus minutis; sepalis cuneato-linearibus acutis, lateralibus longioribus; tepalis spatulatis apiculatis; sepalis impari aequalongi, calcaris ostio magno compresso; lamina labelli cordato pandurata obtusa, sepe cordato-triangula obtusangula. calcaris filiformi ovario pedicellato 2-3 longiori; columna brevissima, pollinarius sinceri *Aeranthi*. *H. G. Rehb. f.*

of his collections were consigned to the water. A few, however, survived the disaster, and from one of them, which flowered in 1836, Bateman's figure was prepared. This has flowers of a pale yellow, with numerous claret-coloured spots. He also remarks that a pale self-coloured variety has more recently been introduced by Mr. Barker, by whom specimens were obligingly forwarded in the autumn of 1838. This would appear to have been a paler

CATLEYA CITRINO-INTERMEDIA (LAMBERHURST HYBRID, *n. hybr.*)

The occurrence of a hybrid between *Cattleya citrina*, with its pendulous habit and bright yellow flowers, and the erect *C. intermedia*, in which light purple is the prevailing pigment, is certainly a matter of considerable interest. When I heard that such an one had been obtained, and was about to flower,

noticed; thus over six and a half years elapsed from the time of sowing before the plant reached the flowering stage. The above name is given by the special request of Miss Harris. It would hardly be correct to describe the hybrid as intermediate between the two parents, in habit at least, for it could not well accomplish this feat without growing sideways, yet it combines the characters of both in a very remarkable way. The plant is erect, and has fine pseudobulbs; the first ovoid, compressed, and 1 inch long, the others gradually increasing in size, the fifth being $4\frac{1}{2}$ inches long, by 1 inch broad, and 10 lines thick, with a slender attenuate base; thus the dimensions are almost intermediate between the two parents, coupled with the erect habit of *C. intermedia*. The flowering bulb bears three leaves, 7 inches long, by $1\frac{3}{4}$ inch broad, lanceolate linear and sub-obtuse; the others have but two leaves, which are somewhat smaller. Here, too, the dimensions are almost intermediate, but the three-leaved character clearly comes from *C. citrina*. On coming to the inflorescence the habit is precisely that of the male parent, for it arches over from the apex of the pseudobulb, the flower being exactly pendulous, and the segment connivent. The peduncle is $2\frac{1}{2}$ inches long, and bears at its apex five acute, broad-based bracts, $\frac{1}{4}$ inch long. It was originally two-flowered, but fearing the plant might not be sufficiently strong to allow of both flowers being fully developed, one bud was removed at an early stage, the peduncle being carried forward $\frac{1}{2}$ inch above the flower, which is borne in the axil of the next bract. The pedicel is $2\frac{1}{2}$ inches long, thickened and yellowish green above, whitish below, the whole with a few faint purplish markings; the segments narrower and more acute than in *C. citrina*, and of a dull creamy-white, inclining to flesh-white, the petals being a little broader than the sepals. The lip is three-lobed, and equalling the segments in length, the side lobes being large, rounded and obtuse, the colour flesh-tint, becoming pale purple at the apex; the front lobe rounded, nearly truncate and minutely apiculate, the margin crisped, undulate, and the colour pale rosy-purple, a fainter shade of the same extending back along the central keels to near the base. Column flesh-white, yellow in front at the base. Thus the flower has the general habit of *C. citrina*, with the colour approaching that of *C. intermedia*, the shape of the segments and lip being tolerably intermediate between the two. The colours seem to have somewhat neutralised each other, and have not come out as brilliant as could be wished. I would suggest that with *C. labiata* var. *Dowiana*, if the cross could be effected, a more brilliant result might be effected. *C. citrino-intermedia* is the name under which it will stand for botanical purposes. *R. A. Rolfe.*

FIG. 11.—ADIANTUM CAPILLUS-VENERIS VAR. IMBRICATUM. (SEE P. 72.)

variety than the one figured in the *Botanical Magazine*, which is of a bright yellow, like the one received a few days ago. The flowers exhale a powerful and most agreeable odour. It is evidently a fine species, and one which ought to be more common in cultivation, as the racemes may bear eleven or even fourteen of its large and handsome flowers. It is also said to succeed well in cultivation. If the two figures mentioned above be compared they look considerably different in the colouring, yet from the acute segments and especially the remarkable trifold and very characteristic lip, I have little doubt that both are forms of the same species. *R. A. R.*

it became a source of some speculation as to how the diverse characteristics of the parents would be combined in the offspring. It flowered in November last, enabling me to record how the difficulty has been solved. The following particulars have been furnished to me by the Messrs. Veitch, as supplied to them by Miss Harris, daughter of the late Dr. Harris, of Lanberhurst, from whom it was received. *C. intermedia* was the seed parent, and the pollen of *C. citrina* was applied on May 10, 1880. On February 19 of the following year the pod was gathered, and the seed sown on the following day. Exactly four months afterwards (June 29), a few seedlings were

TINTS IN FERNS.

FERNS are not usually regarded in any other light than that of providing greenery of various shades for associating with flowers and foliage of brighter hues; and as they thrive well in shady nooks it is generally supposed that they require to be grown under thick shading. This, however, is a mistake—at least, so far as many of the species are concerned, for many sorts not only thrive well when exposed to more light and sunshine, but another charm is added (which in most cases is entirely lost where plants are grown under thick shading), viz., the bright tints in the young fronds. It is pretty generally understood that light and sunshine are necessary for the proper development of bright colours in flowers or foliage, and Ferns are no exception to the rule. It would be a surprise to those who have not given this matter consideration, to find that Ferns produce tints almost as bright and varied as are to be found in any other class of foliage plants. In most cases the bright tints fade as the fronds get more matured; but there is a great variety of shades in the fully developed fronds, and some very pretty forms of variegation which are permanent. Of those in which the colouring is confined to the young fronds *Adiantum macrophyllum* is one of the best

known; under favourable conditions the young fronds have quite a bright crimson hue. *A. Veitchii* is another in which the colouring is very bright. *A. rubellum* and *A. tinctorum* under any conditions show a little colouring, but when well exposed the tints are much brighter. In *A. rhodophyllum* the crimson tinted fronds change to a deep green, while the bronzy tints of *A. Victoria* change to a lighter shade of green. *A. bipinnatum*, similar to *A. macrophyllum*, is a very desirable variety. Many more *Adiantums* might be added to the list, even *A. Farleyense* has quite a bright rosy tint when well exposed; and *A. seutum* may also be included. Of *Pteris* with coloured fronds, *P. tricolor* is one of the most distinct. If well exposed the fronds are not so liable to damp, and the colour is much brighter. *P. aspericaulis* is another highly-coloured variety and the dark bronzy-brown tints give a nice contrast to the lighter shades of such sorts as *P. argyrea*, *P. nemoralis variegata*, and *P. cretica albo-lineata*. The dwarf crested form of the latter, *P. Mayi* may also be added to the variegated forms. *Blechnum latifolia* is very pretty in a young state, the bright rosy-tinted fronds being very effective. *Doodia aspera multifida* is also a pretty little Fern, with a bright red tint in the young fronds. *Lastrea erythrosora* adds another distinct shade, the young fronds being of a pale bronzy hue. *Lastrea cristata variegata*, bright lively green, with linear markings of a paler colour, gives another distinct contrast; *Leucostegia immersa* is a very elegant Fern, with pale bronzy-yellow fronds. The *Gymnogrammas* give another distinct form of colouring; of the silver varieties, *G. peruviana argyrophylla* is one of the best; *G. tartarea*, in which the white farina is confined to the back of the fronds; and *G. Wettenthaliana*, a crested form of *G. sulphurea*, are distinct. Of golden varieties, *G. chrysophylla aurea* is one of the best, and *G. Alstoni*, in which the pinules are curled inwards, showing off the golden under-surface to advantage, is a very effective variety. *Phlebodium glaucum* and *P. aureum* give further variety, the pale bluish tint of the former being very attractive. *Polypodium appendiculatum*, *Dictyogramma japonica variegata* and *Lomaria L'Hermianiera* should also be included in the list of coloured Ferns, and many more might be added to the list of Ferns which give various shades of colouring, but those mentioned will be sufficient to produce a very pleasing effect when grouped together. *Pteris*.

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT THE DELL, EGHAM.

La crème de la crème finds its way to the well-appointed Orchid-houses in Baron Schroder's model garden on the borders of Windsor Park, and once admitted it must be a difficult subject indeed that would not display itself at its best under the management of Mr. H. Ballantine and his careful assistants. On the Baron's part, in all species into which degrees of comparison in the varieties enter quality is the first consideration and cost a secondary matter. If any price in reason is asked, and hence comes the richness in superb varieties and the absence of poor ones in The Dell collection. An example of this is to be found in the matchless varieties of *Odontoglossum*, comprising the wonderful *O. crispum Veitchianum*, the scarcely less beautiful *O. c. apiatum*, *O. c. Sanderianum*, and *O. c. Ballantini*, *O. Pescatorei Veitchianum*, *O. excellens*, *O. excellens Knoxii*, and others, the best dozen of which must have cost hard on £1000, but which could not be matched at any price; and so on through other variable species. At the present time the white and coloured varieties of

Laelia anceps are making a fine show, one of the original type having over a hundred flowers, and a giant specimen of the true *L. a. Barkeriana*, twenty spikes of three and four flowers each; but after all the newly imported forms, the fine old *L. a. Dawsoni* is still not displaced, as a grandly formed

flower, its pure white broad petals being shown up by the rich purplish-crimson of the fore part of its labellum; of this several strong specimens are in bloom, the best having seven spikes of three flowers each. Following on it in the same way is the handsome *L. a. Sanderiana*, which differs from *Dawsoni* in the lighter rosy-tinted colouring of the lip. This in its turn is closely imitated by *L. a. Schroderiana*, which, however, has extraordinarily long and thin pseudobulbs. *L. a. Stella*, of which there are also several fine specimens in bloom at The Dell, seems to be near to *L. a. Sanderiana*, but without the colour on the labellum, the flowers being pure white, with a few crimson lines on the tube of the labellum. The finest of the pure whites, with only a little chrome-yellow and pale green in the upper part of the lip, is the true *L. a. alba* from Mr. Bull's original plant: this is a very pure white, fine in form and substance. Among other rare kinds in bloom are *L. a. rosea*, *L. a. Hillii* with blush flowers and pink lip, and *L. a. Schroderae*, with pale pink sepals and petals, the latter having a rich crimson feather on the tips and bright purplish-crimson labellum. The last-named has just passed out of flower, but *L. a. Veitchiana*, *L. a. Williamsii*, and others are coming on to take its place. All these are grown in a light comfortable intermediate-house, and are in the highest perfection. The showy reddish-orange *Laelia flammea* is also in bloom in the same house.

Cattleyas.—Among the *Cattleyas* the varieties of *C. Trianae* now make the best show, it being their season. *C. T. Schroderiana* holds its own as the best formed flower, fine at all points. *C. T. Russelliana* is in bloom in several specimens, and each year seems to strengthen its claim to distinction, as in the case of *C. T. Osmanii*, which for the bright velvety-crimson of its labellum is unmatched. *C. T. alba* and other rare kinds are in flower, as well as many of the new hybrid *Cattleyas* and *Laelias* in bud. Among these two plants of *C. exoniensis* in full bloom present attractions which few of the newer arrivals will attain. It will be a long time before *exoniensis* goes down in name.

The Dendrobiums and Cypripediums.—The former, which are so well grown, give great promise of flower on stout, clean growth, many of the *D. superbum*, *D. nobile nobiliss.*, *D. n. Cooksoni*, and others, being already prominent in bud. The show in their houses at present depends much on the graceful sprays of *D. bigibbum*, *D. superbiens*, *D. endocharis*, *D. enosmum leucopterum*, *D. aureum*, &c., whose display is supplemented by the varied flowers of the *Cypripediums*, of which *C. Lecanum superbum* ×, *C. vexillarium* ×, *C. Argus*, *C. nitens* ×, many *C. Spicerianum*, *C. Harrisianum superbum* ×, and *C. cananthum superbum* × are in bloom, the two last-named being excellent flowers, which will be deemed good as long as *Cypripediums* are grown.

In another house, the centre bed of which is occupied by a fine show of *Cologyne cristata*, including good plants of the pure white *C. c. alba*, are the collection of varieties of *Cypripedium insigne*, many of them large plants and all well bloomed.

Calanthes, &c.—In a warm house partly furnished with grand specimens of stove plants, as many of the larger Orchid-houses are at The Dell, the *Calanthes* are now making a fine display here as in other places. *C. Veitchii* makes the groundwork of the show with its cheerful rose-pink flowers, and with them the pure white *C. Cooksoni* ×, the rose and crimson *C. Alexandrae* ×, the neat and bright rosy-carmine *C. lentiginosa carminata* ×, and other new hybrids are in bloom, overhead being a fine show of *Phalenopsis* flowers in great profusion, the pure white *Saccolabium Heathii*, the equally pretty white *S. Harrisianum*, with nine spikes, the whole making a very effective display among the tropical foliage plants, of which a specimen of *Alcaesia Veitchii* with foliage 4 to 5 feet in length, the plant being about 25 feet in circumference, may be mentioned as an example. Also as an instance of high culture in this house should be noted a large specimen of *Phaius Wallicii* with three growths

with two stout flower-spikes each, and two growths with three each.

The smaller intermediate-houses have in bloom a lot of *Lycaste Skinneri*, other *Lycastes*, and *Odontoglossum Insleyi splendens*, *O. aureum*, fine specimens of *O. pulchellum majas*, *Cologyne barbata*, huge *Cymbidium Lowianum*, throwing up well; *Vandas*, in good health and flowering condition; *Epidendrum xanthinum* (always in bloom); *E. evectum* and other *Epidendrums*; and noteworthy in a cool corner near the glass a fine tuft of the now very rare *Cypripedium Fairrieanum*, which hothouse treatment has almost exterminated from among us.

Odontoglossums and Masdevallias.—In the cool-houses the *Odontoglossums* are beginning their show for the season, but as yet none of the phenomenal varieties are open; some good *O. Pescatorei*, the pretty, distinct and fragrant *O. Sanderianum*, *O. Andersonianum*, however, are in flower, with some fine *O. crispum*; good bright masses of *Masdevallia ignea*, one of a rich purple, *M. Lindeni grandiflora*, some large *M. macrura*; the pretty *M. polysticta*, and the darker spotted and short tailed *M. p. brevior*, the scarlet *M. racemosa*, *M. hieroglyphica*, *M. amabilis lineata*, with plenty of buds on *M. Shuttleworthii*, *M. leontoglossa* and most of the other *Masdevallias*, while, as unmistakable evidence of good culture, appeared a stout spike, like a head of *Asparagus*, on *Odontoglossum brevifolium*, and a grand and numerous budded inflorescence on the pretty violet *O. Edwardii*, which is, like *Oncidium macranthum*, only manageable for any length of time under strictly cold treatment.

Disas.—The *Disa grandiflora* are another example of fine culture at The Dell. Last year their great vigour was noted, and this year it is still maintained; but even the home-grown plants in the collection are put in the shade by some specimens in 18-inch pans, which had been purchased since last flowering-time from Messrs. James Backhouse & Son, of York, where the plant is largely cultivated in an ordinary greenhouse. The pans at The Dell have each ten or a dozen crowns as thick round as ordinary Leeks, and are, like others still remaining at the York Nurseries, quite a revelation in *Disa* culture; in fact, the plants are grown to a gigantic size, almost beyond recognition. They are potted in turfy, sandy peat, with large lumps of sandstone among it, and are grown as marsh plants. As extra fine and rare in flower should be mentioned *Phaius Sedenianus* ×, a cross between *Calanthe Veitchii* and *Phaius grandifolius*; its yellowish-white sepals and petals are luridly lighted up from the base by a rosy flush, and the labellum, which has much of the form of that of *C. Veitchii*, has also its pleasing pink tint. Another pretty novelty is *Phalenopsis Boxalli* with a numerous flowered spray of yellow flowers barred with chestnut-brown; and the rare *P. intermedia* has a fine spray of twenty-five flowers. Of *Phaius tuberculatus*, were two well flowered plants. The *Phalenopsis*-house, too, is brighter by a row of the pretty blue *Eranthem pulchellum* in thumb-pots, each plant like a little bouquet.

The house of *Imantophyllums* is just showing up flowers; the fine collection of scarlet *Nerines*, which last year showed over 500 spikes, seem likely to beat that record this year; the house of *Nepenthes* is attractive and in good order; the *Camellias* about to make a fine display, and all the other things—fruits, flowers, and vegetables—quite up to the usual high standard set up in this fine garden.

LAELIA CRAWSHAYANA.

A flower of this very rare *Laelia* has been sent to me by the Messrs. Veitch, of Chelsea, and as they had not seen it at the time of publishing their monograph I may add a few words about it. It is about intermediate in size and general appearance between *L. albida* and *L. autumnalis*, the colour being that of a light-coloured form of the latter. Fortunately, I have been able to compare it with living flowers of both these species, also with those of *L. anceps*, and after doing so I believe it to be a natural hybrid

between the two first-named. *L. anceps* has been suggested as one of the parents; but, as Mr. Kent remarks in the letter accompanying it, there does not appear to be the slightest trace of this species about it. The front lobe of the lip and the keels are almost precisely those of *L. albida*, and there is so much of the general appearance of this species about the plant that I do not think it can possibly be a small-flowered form of *L. autumnalis*. As far as I can tell from a single flower, it appears to be as much intermediate in character as do those hybrids in which the parentage is known. It would be interesting to hybridise these two species together, and note the result. *R. A. R.*

LIPARIS MINUTIFLORA.

This curious little species, of unknown origin, but probably Indian or Malayan, is at present in flower at Kew. The pseudobulbs are 1½ inch in length, leaves 3-6 inches long, habit tufted. The flowers, which are pale green in colour, are only one line in diameter!

ANGRÆCUMS AT THE CLAPTON NURSERIES.

Following the rich display of flowers of *Angræcum sesquipedale* at Messrs. Hugh Low & Co.'s, are fine batches of *A. citratum*, and *A. hyaloides*, profusely furnished with flower-spikes; an occasional plant of the rare *A. fastuosum*, *A. articulatum*, *A. Ellisii*, and some presumably new *Angræcum*s, among which the new and fine pure white *A. calligerum* is just going out of bloom. The *Odontoglossum*-houses also have a good sprinkling of the best forms of *O. crispum*, the Clapton form of *O. mullus*, *Wilckeanum*, &c.; and the *Cypripedium* and other houses have some other interesting things in bloom, notably a finely-formed white *Cattleya Trianae* with faint lilac tinge on its well-rounded labellum.

PHALÆNOPSIS SCHILLERIANA VESTALIS.

This extremely rare and chaste variety, which was original described in the *Gardeners' Chronicle*, from a plant which flowered in the fine collection of *Phalænopsis* at Messrs. Hugh Low & Co.'s nurseries at Clapton, has again appeared there. All that need be said of it is, that it is a pure white *Schilleriana*, not showing any trace of the rose tint of the type. The lower halves of the lateral sepals and the labellum have a few yellowish dots, and the base of the labellum a yellow tinge with a few minute brown spots, all of which in no way detract from its qualities as a white flower. It is a fine plant, of the highest merit. Also in bloom are the neat flowered *P. denticulata*, and such of the other *Phalænopsis* of the season as have been able to escape the scathing influence of the London fogs, which, however, never seem to lessen the vigour of the plants themselves. *P. s. vestalis* has foliage identical with that of some of the varieties of the *P. s. Schilleriana* which do not so much display the silver-grey bars generally seen in that species.

THE HERBACEOUS BORDER.

A SELECTION OF HARDY HERBACEOUS PLANTS.

Those who grow these plants should grow, instead of a few old species of Michaelmas Daisies, Solidagos, Columbines, Monkswoods, Campanulas, Veronica's, selections of the distinct and good subjects which are procurable at any nursery for a trilling outlay, and which are better worth growing than much of the contents of many herbaceous borders. As an assistance to those contemplating the purchase of plants I give a list of the names of subjects obtainable at a small cost.

Achillea millefolium roseum, a handsome form of the Milfoil, with deep lake-coloured flowers, freely produced even during hot weather during August and September. Height 2 feet. *A. ptarmica flore-pleno*, beautiful very small white flowers, in dense

trusses; it is ordinarily known as the Sneezewort; excellent for cutting, and a very free grower. Height about 1 foot, and flowering in July and August. The stools require transplanting frequently, owing to its habit of pushing forth long underground stolons that soon take possession of the surrounding ground.

Aconitum Napellus bicolor.—This variety and the white-flowered form, *Aconitum Napellus album*, are the best plants of their class, growing to a height of 4 or 5 feet; they are very showy during the months of June and July. The plants thrive well in most soils, but a deep moist loam is the most suitable.

Anemone japonica alba (syn. *Honorine Jobert*) is an ornamental subject, blooming from August to October. The flowers are of the purest white, and are set off by fine bold foliage. The flowers being supported on erect footstalks from 2 feet to 3 feet in height, make a very pleasing display. *A. j. rosea* and the original species, *A. japonica*, with numerous large red flowers, are also very desirable plants, and may be advantageously grown with the other species. They all require a deep, well enriched soil, and to be freely watered in the early autumn. Propagation is effected by division of the stools and roots, every portion of the latter, if placed in sandy soil in the month of October and kept in a sandy pit, will form shoots, and ultimately a plant.

Armeria plantaginea, the Giant or Plantain Thrift, a native of the South of Europe, has large red flowers, growing upon strong footstalks 12 inches in length. It is propagated freely from cuttings, and is a very showy plant for the front row in a bed or border. The flowering time is the month of June.

Bocconia cordata, or Plume Poppy, belonging to the natural order Poppyworts, bears long terminal panicles of inflorescence of a brownish colour. It is one of the most showy of hardy plants, growing to a height of 6 feet. It is suitable as a back row plant, or to grow as a specimen on the lawn, or in prominent niches in front of shrubberies.

Campanula persicifolia alba flore-pleno averages 3 feet in height, has large double flowers, of good substance, and is a valuable subject for cut flowers. *Campanula latifolia macrantha* is a showy variety, 3 feet in height, bearing abundantly large blue flowers.

Campanula urticifolia flore-pleno.—The German Nettle-leaved species of which this is a double form is a desirable acquisition, averages 2½ feet in height, and the flowers are blue.

Delphinium formosum, and the improved *D. formosum Belladonna*, the former a rich dark blue, and the latter with bright azure-blue flowers with a white centre, are amongst the best of herbaceous plants, and should be found in every garden, being quite hardy, easily propagated by seeds and by division of roots, and flowering freely. The spikes of bloom appear at the apex of growths averaging 3 to 4 feet in height. Besides the two above-named there are some scores of hybrids, probably the result of hybridising between the above and *D. cashmirianum*, and comprising double and single-flowered varieties. Some of these latter, it may be well to add, sport away from the normal blue colour to rosy-lilac, variously edged with white, &c., thereby affording much greater variety than is generally supposed.

Dictamnus fraxinella, the Ash-like Dictany, or Fraxinella, a favourite old herbaceous plant, of which both purple and white-flowered forms exist, is a very hardy plant, a native of Germany. It grows into neat bush-like form, crowned with spikes of flowers, which generally reach 3 feet in height. Both foliage and flowers are ornamental.

Dielytra spectabilis is one of the most beautiful and graceful hardy plants yet introduced into our gardens. The plant had been long heard of, and dried specimens found their way into this country some years before Mr. Fortune sent home living examples from Chinese gardens. The plant has been named "Ladies' Locket-Flower," and "Pig-tooth Flower," from a fancied resemblance the flowers bore to these

objects. The plant possesses Fern-like foliage, is quite hardy, succeeding well in the same spot for many years together when planted in light rich soil in a sunny aspect. It is very easily propagated by division, and by cuttings taken from growing shoots during the summer months. No garden should be without this plant, and it is to be regretted that the prophecy concerning it when first introduced—that it would find its way into every cottage garden—has not long ago been verified.

Erigeron speciosus superbus.—This Californian Composite possesses a multitude of large lilac-purple flowers, and should not fail to be found in any collection of herbaceous plants, however small. Its average height when in bloom is about 3 feet, and the season of flowering from July to September—a time when flowers are getting somewhat scarce. It is readily propagated by division of the plant, and thrives well in ordinary garden soil.

Funkias, both for beauty of foliage and fine Lily-like blooms, are all very desirable plants, more especially such forms as *F. ovata aureo striata*, *F. spatulata foliis variegata*, *F. undulata medio variegata*, and *F. Fortunei foliis variegata*. Introduced from sunny Japan, they require a dry warm situation and porous sandy loam soil.

Gentiana acanthis.—The lovely Welsh *Gentianella* is not nearly so difficult to grow as is generally imagined, and forms neat patches, so that it may be grown as an edging plant in light sandy loams. Its lovely intensely blue flowers, large, compared to the size of the plants which produce them, have a peculiar fascination for most persons.

Geums, allied to *Potentillas*, comprise at least three distinct and highly meritorious species in *G. aureum*, *G. coccineum flore-pleno*, and *G. miniatum*, comprising respectively yellow, scarlet, and brick-red coloured flowers. They all thrive best on a dry warm site, or upon rockwork; the last-named is a strong variety, flowering the whole year through more or less.

Helianthus multiflorus flore-pleno and *H. rigidus* well represent the showy perennial Sunflowers, and are the best to grow; the former is the double-flowered form. Those who prefer showy single flowers should choose *H. multiflorus major*. All are readily propagated by division of the old stools in the early spring months.

Helleborus niger (the true Christmas Rose) and *H. angustifolius* are the best of an interesting genus which bloom about midwinter, and only require a deep, rich, well-drained soil, and partial shelter from the hot sun of summer, to succeed well.

Hypericum calycinum, called by some writers the Rose of Sharon. I do not find it, however, amongst Dr. Tristram's lists of plants recorded as belonging to Palestine. *Hypericum calycinum* is as showy when in bloom as it is hardy and enduring. It will even hold its own upon meadow lands whereon horses habitually graze. As a clump in the herbaceous borders and for edgings it is highly suited. *H. olympicum*, a species from the Levant, is also a fine shrub-like border plant, averaging 3 feet in height, and bearing abundantly yellow flowers about the size of a florin for many weeks from the beginning of August.

Iris germanica in its many varieties is an indispensable plant. *Iris Kämpferi*, the water-loving Japanese species, are also desirable for moist places, whilst for edgings and front-row plants *I. pumila*, the Crimean Iris, and *I. nudicaulis* add interest to any collection of hardy flowers. *W. Earley*.

THE RAINFALL OF 1887.

We read in the *English Mechanic* of January 14 that Mr. G. J. Symonds has issued his preliminary note on the rainfall of 1887. Taking eleven of the oldest established stations out of 2000 which report to him, he finds that the deficiency of the fall compared with the average for 1870-79 ranged from 15 per cent. at North Shields to 11 per cent. at Seaford, co. Down. It is very unusual, says Mr. Symonds, for the fall of rain to be short of the average by more than one-third; but out of the eleven stations above quoted this has been the case at three, and at another it is within one per cent. of it. While, therefore, at some stations—such, for example, as London, where the fall was, in 1864 only 16.93, and in 1874 only 18.82—the fall has not

been unprecedentedly small, there has apparently been a universal deficiency, and in some localities it has probably been without recorded precedent. It appears from such records as are available that 1787 was also a rather dry year in the South of England; but in the North of England and the South of Scotland the rainfall was above the average.

Mr. H. Southall, writing from The Graig, Ross, Herefordshire, reports a deficiency of 25 per cent. from his thirty years' average. On the other hand, Mr. E. Bailey-Denton, writing from Stevenage, Herts, says the total rainfall of the year 1887 amounted to 21.46 inches, which is 4.11 inches less than the average of the last fifty years; but many will hardly realise the fact, remembering the heat and drought of last summer, that during the last seventeen years there have been several drier seasons in his district. For instance, comparing the local records, he finds that in 1881 there were only 18.68 inches; in 1871 there were 19.50 inches; and in 1870 there fell 20.12 inches, thus showing that the extra inconvenience to which his district was subjected was more owing to the comparatively long consecutive periods during which no rain fell than to the total deficiency of the year. Mr. Bailey-Denton goes on to say that his records should convey a homely lesson to us as a practical nation: for if we had, throughout our rural districts, stored on the surface the rainfall of last April and May when we had a superabundance, instead of allowing it to run to waste, the painful experiences of the latter part of the summer and the earlier part of the autumn would have been avoided, and much unprofitable, though absolutely necessary, expenditure of money incurred in the carting of water would have been saved to farmers and land-owners.

PLANT NOTES.

OVERGORGED SARRACENIAS.

THE collection of *Sarracenia*s cultivated at Kew is made up of large strong specimens of most of the kinds, and they are invariably very well crowded with strong well developed pitchers. Last summer they made exceptional growth and in September the collection was unusually good. But about a month ago the pitchers began to decay, in some cases the decay commencing in the middle, in others near the top of the pitcher and on examining we found that this decay was caused by the putrefying mass of insects, chiefly large blue-bottle flies, which filled the pitchers up to the point where the decay first commenced. A pitcher of *S. Drummondii*, which measured a little over 2 feet in length, was filled to within 5 inches of the mouth with dead flies, and so on through the whole collection, almost every pitcher being well charged with a rotten mass of the remains of insects. The stench caused when the contents of the pitchers were disturbed was very strong, and in the upper part of the mass in some pitchers we found living white maggots, probably the larvae of some of the caught insects, which had hatched in the putrefying bodies of their parents. We have washed out most of the pitchers and hope, that by so doing, we shall save a few till the spring, when new pitchers will be developed. Until this year we have taken the precaution to stuff a little cotton-wool into the mouth of the pitchers, just down far enough to be out of sight, and this has effectually prevented any such disaster as has occurred this year, and without affecting the health of the pitchers. Of course the wool is not required until the pitchers are fully developed, as there are no flies much to bother them till after the bulk of the new growth has matured.

Two ideas have suggested themselves to me as the outcome of this apparent overgorging in *Sarracenia*s—1st, That the secretion found in the pitchers, which is stated to be less than a drachm, is not necessary to the destruction of the insects caught in them. It has been stated that, "without doubt" the secretion found in the tubes of the *Sarracenia* is intoxicating, or anæsthetic, or narcotic, or by what-

ever word you may prefer to indicate that condition to which these insects succumb," (Professor Asa Gray.) The enormous mass of dead insects in the pitchers described above could not have been affected by the few drops of this secretion contained in each pitcher. The second idea is that, whether designedly or purely the result of accident, the pitchers, by entrapping such immense numbers of insects, do collect what must prove a powerful stimulant to the roots of the plants, when, by the decay of the pitchers, their contents is necessarily deposited on the ground directly above where the roots find nourishment. *W. Watson, Kew.*

NEW FORMS OF PHLOX DRUMMONDII.

TWO new forms of *Phlox Drummondii* are announced from the Continent; one is named "fimbriata." In this case the pips, instead of having the smooth-edged circular form, are partly fimbriated and partly three-toothed, the centre teeth being almost twice as long as the lateral ones, and all are distinctly bordered with white; the flowers are variously coloured in the centre, some maroon-crimson, others violet-blue, purple centre; but whatever the colour, the whole bordering is uniform. The other is named "cuspidata," or Star of Quedlinburg, and in this case it is a selection from fimbriata, but the centre teeth of the petals, five in number, are four or five times as long as the lateral ones, and project beyond them in the form of spines from a third to a quarter of an inch long, and here also is found the white margin alike to the petals and the spines. The latter is a very curious form, and shows how the old fancies are being overthrown, for, as in the case of the *Verbena*, the fanciers of *Phlox Drummondii* have laboured to secure the smooth, stout, rounded edged, and now here is a reversion to star-shaped flowers. Whether these novelties in form will find favour in this country remains to be seen. *R. D.*

COFFEE AT HOME.

ABOUT Christmas time, as if to show what could be done in the way of furnishing berried plants, we received from Kew a branch of the Coffee shrub densely laden with its berries. The branch evinced such good cultivation, and was so beautiful with its deep green glossy leaves, forming a setting for a profusion of brilliant berries, that we sent it forthwith to the artist. Unfortunately the necessarily reduced size of the illustration, and the absence of colour are formidable obstacles in the way of reproducing the beauty of the original, but even in black and white the profusion of the berries is manifest (fig. 12). Planters speak of the berries as Cherries, with which they have little in common save the colour. The portion utilised is the seed. With the living plants in the houses, the museums in which the products and processes of manufacture are exhibited, the herbarium in which dried specimens of the various species and their allies are contained, the picture gallery in which are displayed Miss North's beautiful drawings, the laboratory in which the minute anatomy and chemical constitution of the plants may be investigated, and the library wherein the student may study the literature of the subject. Kew may well be proud of the completeness of the materials and opportunities she offers to the student. Those who are not interested in research will nevertheless find that the Coffee shrub, apart from its interest, is a beautiful shrub for the warm greenhouse or stove, as it is beautiful alike in leaf, in its white Jasmine-like flowers, and in its fruit. The cultural conditions are thus summed up in *Nicholson's Dictionary of Gardening*:—A turfy loam and sand, abundance of water, and ample pot room. The plant is readily propagated from cuttings. The following note relating to the fertilisation of the flowers in India is so interesting that we venture to reproduce it from the columns of *Nature*:—

"The Jasmine-like flowers of the Coffee are borne in clusters in the axils of the leaves, and appear

simultaneously all over the estates. After a prolonged drought of one or two months, or even more, at the beginning of the year, there is generally a heavy fall of rain, sometimes lasting only an hour or two, sometimes continuing for two or three days; the amount that falls must be enough to saturate; the ground, and should not be less than 1 inch.

"In from six to eight days from the time of the first shower, the flowers burst into full blossom, last for a day, and then drop off. On the evening before the blossom is fully out, if the flowers are examined, it will be found that they are partially open, the stigma being protruded and receptive. During the night the hum of insects can be distinctly heard, and I am of opinion that the flowers are largely fertilised by night-flying insects which carry pollen from those flowers which happen to be open rather before the others, as some are delayed. On the following morning all the flowers will be found open, and the field of Coffee presents a sheet of white. These flowers are frequented by immense numbers of bees, of two kinds, one about three-quarters of an inch long, and black, the other smaller, and with white bands round its abdomen. The stigmas now are covered with pollen, and the anthers bursting, and the larger of these bees may be seen buzzing from flower to flower sweeping up the grains of pollen between its front legs, and rolling them into balls. Long before evening all the anthers are exhausted of pollen, and the insects have departed. Besides bees some butterflies visit Coffee.

"The Coffee plant, by being protogynous, is intended by Nature to be cross-fertilised, but owing to all the plants in one clearing being usually grown from seed of a single estate, there must be a great deal of interbreeding, more especially as all the Coffee of Ceylon and most of South India is supposed to be descended from a single plant introduced into Batavia about two centuries ago. This may have something to do with the manifest deterioration in stamina of the younger Coffee."

DINNER-TABLE DECORATIONS.

AS time goes on fashions constantly change. The rather heavy arrangements of groups of plants and designs in flowers on the table that were fashionable a few years since would hardly be tolerated in a town or country house at the present time, when the style in vogue is lighter, and more elegant than formerly.

Having to provide large quantities of materials for this purpose for the London abode, and also when the family is in the country, the mention of a few simple arrangements that we use here may be of service to others. The size of the dinner-table is not material, as, of course, the quantity of materials used, is regulated according to the number of guests laid for at the table. One pleasing arrangement consists of sprays of *Adiantum cuneatum*, laid on the centre of the cloth, as a groundwork with single flowers of *Eucharis amazonica*, with the same species of Fern standing in small globes; and single spikes of *Eucharis*, cut rather long, with from three to four open blooms on each, are placed in tall silver cups also with the Fern round them. The centre of the table has one, two, or three light feathery Palms in silver vases, according to the size of the table, the *Eucharis* in silver cups being arranged down each side of the table, and the globes of *Eucharis* flowers standing between the groundwork of *Adiantum cuneatum*, on which these are placed, showing the latter off to advantage.

Sometimes white *Chrysanthemum* blooms are employed instead of *Eucharis*, the more useful varieties for the purpose being *Duchess of Manchester* and *Fair Maid of Guernsey*. We also make use of forced Roman Hyacinths, turning the bulbs out of their pots, and placing them in damp moss, so that the foliage can be retained. For a strong contrast a dark red silk cloth laid along the centre of the white one is sometimes made use of, and bordered with the leaves of *Gros Colmar* Vine, which being of rich colours have a good effect. Some of the Vine leaves are also laid about on this red cloth, and some blooms of *Chrysanthemum roseum superbum* variety either in globes or silver cups, about three or four blooms in each, are stood on this

cloth each side, a centre being made of the same variety of Chrysanthemum cut off a good length and stuck in pots of sand and placed in silver vases—sufficient to form small plants. Another arrangement is a pale blue silk cloth for the centre of the white one, and edged with short sprigs of the pure yellow sport from the Golden Queen Holly and yellow Chrysanthemums employed in the same way as in the former arrangement. In this case the Holly sprigs are laid about on this cloth. Another arrangement consists of plants of Poinsettia pulcherrima in vases for the centre of the table, a dark blue cloth being used in this case, and bracts of the same cut ather long in the stem, together with their foliage, and placed in silver cups with leaves of the Gros Colmar Vine as edging, and laid about on the coloured cloth. When a gold service is used at this season of the year, plants of Erica hyemalis are very useful for filling the vases.

The above are only a few out of the many other arrangements made use of, and which are particularly in request in the autumn and early winter months. Single Dahlias in yellow, white, and scarlet, are very useful, as are green leaves of the Vine. Very large quantities of Adiantum cuneatum need to be grown for the supply during the London season if the family reside there. The hardy American Azaleas we find very useful at that time, especially the large yellow one, of which we grow large numbers. Roses of various colours are much sought after, as also Azalea indica alba, of which we grow a large number of plants. *E. Ward, Howell, Bromsgrove.*

CHRISTMAS ROSES.

The imported plants of Helleborus niger from North Germany, of which I have grown a large number, yield many pretty varieties, some of them with green stalks and the pure white flowers which distinguish the finer garden sorts, but the flowers are small and short-stalked. Those from the valleys of the Austrian Tyrol are of a larger sort, frequently H. niger major, such as is grown about Bath. It would appear that the Hellebores increase in size and improve in quality as you proceed southwards, probably as a result of more favourable climatic influences, continued through many centuries. In this way we find the larger form, H. n. major, in the Austrian Tyrol, and the larger H. n. altifolius or maximus on the south side of the Alps, both in Austria and Italy. I have had a good many Hellebores collected recently from the southern habitats, large-leaved varieties being alone selected, and they contain many examples of altifolius as well as those of the angustifolius group, resembling the well known Brockhurst and Riverston varieties. It is too soon to speak precisely, as it takes some time for plants to recover and display their proper characters. These plants were six weeks on the way from Italy, and it speaks well for the vitality of the Hellebores that they have survived and are all doing well.

The large forms of altifolius thus found growing wild have the same differences in leaf which are noticeable in our garden varieties. The petioles are from 12 to 20 inches long, with large spreading leaves. The lobes in some leaves are deeply jagged, and in others smooth-edged; some have wide, almost obovate lobes, whilst in others they are narrow, and the whole character resembling the angustifolius group. The colouring of the stalks also varies, some being pink, others mottled with purple, and some green throughout. In all the root is similar, like that in our altifolius, and quite different from the common H. niger.

Mr. Ware's new varieties appear to be from some new district, as the characteristic peculiarities of altifolius and niger seem to be combined. Probably they came from the Austrian Tyrol. His H. n. rubra, which is described as the most distinct and novel of the group—a veritable red Christmas Rose—is the most remarkable. Its stalks are deep purple, and the flowers are deep pink, and it has the deepest pink coloured pistils of any. This is the dis-

tinguishing features of the tall-growing altifolius; but rubra is as dwarf as the ordinary niger. This, then, is a new sort, of much interest, and should be in every collection. Mr. Ware's caucasicus is, as I have previously stated in your columns, and as far as I am able to judge now that it is in bloom, the H. n. vernalis of Don (see Sweet's Flower Garden, vol. v., p. 186). It agrees also nearly with Haynes' H. n. altifolius, as

dropped for the future. It is a well marked and interesting variety, with the peculiar pink tipped styles, but with a very dwarf habit, the flower and leaf-stalks being only about 6 inches high. The flowers are small and of poor substance. Mr. Ware describes it as intermediate between major and maximus, but it is a much smaller plant than either of these. It also differs greatly from Mr. Poë's Riverston variety, which has this pink styles, but which has long flower-stalks, a larger and purer flower, and long-stalked narrow leaves, belonging to the angustifolius group.

Mr. Hartland sent me specimens of what he considers H. n. vernalis, but I do not consider them so. His is probably the ordinary H. niger, with pinkish colour, exceedingly like that figured by Curtis in the first volume of the Botanical Magazine so long ago as 1786. One of the names Curtis gives for this variety is H. niger flore-roseo. This differs from Mr. Ware's rubra in not having the pink centre, Mr. Hartland says that this plant has been in the South of Ireland since the time of the Hagenots, which is likely enough, as it was the first variety recorded in our botanical literature, and they may as well be credited with the introduction of the Christmas Roses as they are credited with that of the Tenby Dafoedils. *Wm. Brockbank, Brockhurst, Didsbury, January 14.*

Before receiving this communication Mr. Brockbank was good enough to send us excellent specimens of nine varieties. Unfortunately they arrived at a time of editorial pressure, and, moreover, one of persistent black fog; so that their examination could not be attempted till some days after their receipt.

The specimens were easily separable into two groups, or less readily into three. There is the angustifolius set with longer, thinner, paler leaf-segments, which are wedge-shaped, comparatively straight-edged at the base, and generally with finer sharper teeth at the margin, and with larger flatter flowers. In contrast with these is the niger group proper, in which the leaf-segments have generally shorter stalks, are smaller, more coriaceous, darker, not so distinctly wedge-shaped at the base, the margins being more curved and towards the apex more coarsely and crenately toothed. A possible third group may be made to take in the altifolius set, but that is less easily definable.

We append a few descriptive notes taken from the specimens before us, but it must be remembered that we have not hitherto had leisure to compare the specimens with herbarium specimens, or our descriptions with those given in books. It may here be mentioned that Mr. Baker's monograph will be found at p. 132 of our volume for 1877, and valuable notes from Mr. Brockbank, Mr. Archer Hind, and others, in our numbers for December 1, 1883, and January 19, 1884. We take the plants in the order of Mr. Brockbank's numbers. By mid, or deep stellate, we mean a flower whose white calyx appears divided to about the middle, or to a point below the middle. The measurements are rough averages. In the case of the leaf the central segment only is taken:—

FIG. 12.—COFFEE GROWN AT KEW. (SEE P. 76.)

figured in Reichenbach's *Icon. Flo. Germ.*, exii., and is thus probably one of the wild forms of altifolius from the Austrian Tyrol. Mr. Hartland has also sent me flowers of this variety and a characteristic leaf, and this exactly agrees with the leaf figured separately by Jacquin in his *Flora Austriaca*, to which Don refers in his description of the leaf of H. n. vernalis. I think we may, therefore, assume that this is the H. n. vernalis of Don, and it is to be hoped that the misleading name, caucasicus, will be

1. HELLEBORUS "ST. BRIGID" (ANGUSTIFOLIUS).
 Leaf-stalk not furrowed, green; leaf-segment 6 x 1 1/2 inches, lanceolate, tapering at the base into a stalklet about half an inch long; slightly and remotely toothed in the distal third.
 Flower-stalk green; bract broad, concave, whitish.
 Flower nearly 4 inches across, flattish, mid-stellate; sepals obovate; petals (nectaries) half an inch; stamens nearly twice as long as the petals; styles white, about the same length as the stamens.

2. BROCKHURST VARIETY (ANGUSTIFOLIUS).
 Robust; leaf-stalk green; leaf-segment 6 x 1 1/2 inches, oblanceolate, tapering gradually to a stout stalklet more than half an inch long, rather coarsely but evenly saw-toothed in the upper third.
 Flower-stalk green, with a tendency to bear two flowers; bract-ovate-lanceolate concave, greenish, flushed with rose. Flower more than 3 inches across, flat, mid-stellate; sepals rather less than 2 1/2 inches, obovate, obtuse, tapering at the base; petals yellowish; stamens nearly twice as long as the petals; styles white, recurved, slightly longer than the stamens. Perhaps too near to St. Brigid to be worth keeping as distinct, but still distinct in the dentation and form of the segments.

3. RIVERSTON HYBRID (ANGUSTIFOLIUS).

Robust; leaf-stalk green; leaf-segment lanceolate, scarcely oblanceolate, $5\frac{1}{2} \times 1\frac{1}{2}$ inches, gradually tapering at base into a stalklet rather more than half an inch long, rather coarsely and remotely saw-toothed in the upper third, teeth spine-tipped.

Flower-stalk red-spotted; bracts roundish or ovate-acute, concave, entire. Flower $3\frac{1}{2}$ inches across, flat, mid-stellate, white, flushed with rose on the outer side. Sepals $1\frac{1}{2} \times 1$ inch, ovate, oblong, tapering at the base into a green stalk, hence the flower has a five-rayed green star much more strongly marked than in the others; petals less than half an inch; stamens slender, twice the length of the petals; styles about as long as the stamens, and pink. There is no obvious mark of hybridity about this plant.

4. II. NIGER MAJOR (VEITCH, EXETER) (ANGUSTIFOLIUS).

Robust; leaf-stalk slightly furrowed; leaf-segment $6 \times 1\frac{1}{2}$ inches; oblanceolate, tapering at the base into a stalklet about half an inch long, rather finely serrate in the upper third, and with a tendency to subdivision.

Flower-stalk red-spotted; bracts whitish lanceolate concave, lowest one somewhat leafy. Flowers flat, more than 3 inches across, white, mid-stellate; sepals ovate oblong obtuse; petals a quarter of an inch long, stipitate; stamens one-third longer than the petals; styles white, about the length of the stamens.

5. II. BATH VARIETY (COOLING) (NIGER).

Leaf-stalk red-spotted, slightly furrowed; leaf-segment $5\frac{1}{2} \times 1\frac{1}{2}$ inches, oblanceolate, tapering at the base into a short stalklet, less than half an inch long, evenly and shallowly toothed in the upper third.

Flower-stalk red-spotted. Flowers $2\frac{1}{2}$ inches, flat, white, mid-stellate; sepals ovate, oblong, obtuse, petals less than half an inch; stamens spreading, nearly twice as long as the petals; styles white, one-third longer than the stamens. In some respects intermediate between II. niger and II. angustifolius, having longer and more stalked leaflets than ordinary II. niger.

6. II. MISS HOPE'S VARIETY (ANGUSTIFOLIUS).

Leaf-stalks green, slightly red-spotted; scarcely if at all furrowed; leaf-segments oblanceolate-acuminate, with shallow dentations in the upper third only, and with a tendency to sub-division, gradually tapering at the base into a rather long stalklet, that of the central lobe being more than half an inch long.

Flower-stalks, red-spotted; bracts oblong green, flowers nearly 3 inches in diameter; flat, white, slightly flushed with rose on the outer side—mid-stellate; sepals ovate obtuse; petals nearly half an inch, greenish yellow—tipped; stamens twice the length of the petals; filaments white, anthers 2-lobed; proterandrous; styles erect, and as long as stamens; stigmas recurved, white.

7. MADAME FOURCADE (HORT. WARE) (ALTI-FOLIUS).

Petiole red-spotted, only slightly furrowed; leaf-segments $5 \times 1\frac{1}{2}$ inches, oblong lanceolate, tapering at the base into a short stalklet, coarsely and irregularly toothed in the upper half, teeth slightly spine-tipped.

Flower-stalk red-spotted; bract oblong lanceolate, concave. Flower $2\frac{1}{2}$ inches in diameter, pure white, shallow—stellate; sepals $1\frac{1}{2} \times 1$ inch, broadly ovate; petals $1\frac{1}{2} \times 1$ inch; stamens twice the length of the petals; styles about as long as the stamens; stigmas pink.

8. II. CAUCASICUS (WARE) VERNALIS (ALTI-FOLIUS) (GROUPE).

Petiole green, stout, deeply furrowed, especially towards the upper part. Leaf-segments $5 \times 1\frac{1}{2}$ inches, oblanceolate, tapering at the base into a short stalklet more than half an inch long, markedly spinose—dentate in the distal third.

Flower-stalk thickly spotted with red; bract broadly lanceolate, recurved. Flowers 3 inches across, flattish, pure white, flushed with rose outside; deep stellate. Sepals $1\frac{1}{2} \times 1$ inch, obovate oblong, leaving comparatively deep interspaces between them like the sails of a windmill; petals half an inch, greenish-yellow, stipitate; stamens only slightly exceeding the petals in length, much shorter than the white styles.

Remarkable for the deeply furrowed leaf-stalk, the coarsely-toothed leaves, and the narrow sepals having

deep interspaces between them. This is not true caucasicus of the books, nor is it the caucasicus of the Hort. Barr., but whether it be vernalis, as Mr. Brockbank suggests, we cannot say.

9. II. NEW SEEDLING, W. BROCKBANK (NIGER).

Leaf-stalk green, sparingly spotted, scarcely if at all furrowed; leaf-segments $4 \times 1\frac{1}{2}$ inches, oblanceolate, tapering at the base into a short stalklet less than half an inch long, coarsely crenately toothed in the distal third, with no tendency to subdivision.

Flower-stalk green, sparingly spotted. Flowers $2\frac{1}{2}$ inches in diameter, permanently cupped, pure white; sepals roundish, narrowed at the base; petals half an inch long, yellowish, shortly stalked; stamens twice the length of the petals, spreading; styles as long as the stamens, erect; stigma recurved, white. A form of niger remarkable for its deeply cupped flowers.

10. II. VERNALIS, HARTLAND, CORK.

Leaf-stalk green, furrowed segments $4 \times 1\frac{1}{2}$ in.; obovate-lanceolate, coarsely serrate. Flower-stalk red-spotted, with a tendency to branch; bract oblong ovate; flower flat, $2\frac{1}{2}$ inches in diameter, mid-stellate; sepals white, flushed with rose, showing a tendency to increase in number, ovate-oblong, rounded; petals yellowish, stalked; stamens one-third longer than the petals; styles white considerably longer than the stamens. This is a pretty form of niger evidently quite different from Mr. Brockbank's No. 8, known in Ireland for at least two hundred years.

Mr. F. C. Heinemann, of Erfurt, sends us a number of seedling Helleboreas, which unfortunately were in bad condition when we examined them. They were seedlings from orientalis, having graceful, pendulous flowers, some pure white, others with numerous purple spots upon a white ground, and others again of a pale purple colour, either with or without spots.

Seedling No. 2 seemed to us in the state in which we saw it to be the most noteworthy, it being of a purplish colour, with reticulations and spots of the same colour, but darker.

THE ORCHID HOUSES.

ODONTOGLOSSUMS.—If the potting of the cool-house Odontoglossums was attended to in last September the plants should now be getting well established, and will not be easily disturbed during the work of cleaning and overhauling, and will also be in a fit state to pass through the flowering season. Care should be taken not to give more water at the root than is necessary, for if the plants are kept in a saturated state the compost will rapidly decay and become sour. Those having cool-house Orchids will find it a great relief to have got their potting done in the autumn, as the task of keeping the plants clean will take much of their spare time at this season, as not only is it necessary to guard constantly against the ravages of slugs, but if aphids be allowed to remain a few hours on the buds the flowers will be deformed.

Thrips are the worst plague a gardener can have in the Odontoglossum-house, for if they are present they will generally be found hidden amongst the new growths, and are then difficult to eradicate. When dark green spots are found on the tender leaves it is a convincing proof that these insects are about the plant; and when the flower-spikes show themselves the thrips seem to have a greater liking for these than for the foliage, and leave the latter and conceal themselves under the flower-buds. As prevention is better than a doubtful cure, I have found flowers of sulphur to answer very well, taking a small quantity in the hand, into which dip a soft brush and draw it upward on the spike, keeping the other hand underneath the brush to catch any sulphur that would otherwise fall on the plants. Take care to keep the sulphur and brush quite dry; but even this substance will not drive the thrips out if they once get possession of the flower-buds.

Late Potting.—If there are any Odontoglossums or Masdevallias that were not potted in the autumn, owing to the flower-spikes being then too far advanced, and they now require it, the potting may be done at this season, and the plants will be established quickly if placed in a moist atmosphere with a temperature of 50° and 55° . I find it necessary with Masde-

vallias to dip into or sponge occasionally with a weak mixture of tobacco-water, thrips and red-spider rapidly disfiguring the leaves of all, especially the Chimara section. It is a good rule to fumigate the Cattleya-house with tobacco before many of the C. Trianae open their flower, although we may not have observed any thrips there.

Cattleyas and Laelias in pots should be carefully watered for some time yet, as their requirements will vary according to the interior arrangements of the houses, the kind of stages, &c. We find that once a week is sufficient for Laelias and Cattleyas standing on ordinary stages. Until the season is more advanced the night temperatures should be kept at about the following figures:—Phalanopsis-house, 65° ; East Indian-house, 63° ; intermediate, 58° ; the cool-houses, 50° ; and let the day temperatures rise 3° to 5° with artificial heat. Keep the fires in check on bright days, and let the temperatures rise several degrees with sun-heat. C. Woolford, Downside, Leatherhead.

PLANTS UNDER GLASS.

Plumbagos.—Only three species are found in cultivation under glass, viz., P. capensis, which yields a profusion of its pale blue flowers during the summer and autumn. This species, if grown in a warm, light position, and cut back after flowering, will soon break away afresh, and flower again; and this treatment may be repeated till well on in the autumn. Plumbago zeylanica (alba) is very similar to capensis, only that it is white, and is not quite so hardy. Neither of the two are very amenable to pot culture when aged; they do best when treated as climbers. The other species usually met with is P. rosea, or its improved varieties, coccinea or splendens; the last-named is grown in large quantities for winter decoration, and deserving of a specific name. The plant is of easy culture.

By putting in cuttings now, taken from plants which have been flowering during the past few months, they soon root, and may be potted off in the usual way, using a light friable loamy soil. It is better to get up young plants annually, as these are more manageable, and produce finer spikes of flower than old specimens. This species being an inmate of the stove or intermediate-house will not succeed where P. capensis does well, but its habit is considered by many to be preferable to that species, and it is well suited for pot culture. Nice bushy plants in 48's or 32's are very serviceable.

Euphorbia jacquiniiflora Julgens.—This plant is also best raised annually from cuttings. When it is grown in a pot, single plants with three or four shoots, laden with their handsome orange-scarlet flower bracts, are very telling things when associated with other plants, and as cut flowers lasting for several days in a fresh condition. The present is a good time to put in cuttings. Insert them singly in very small pots, using a fine sandy soil; when thus early struck single cuttings may be grown by autumn into handsome plants. A brisk stove temperature is best suited to the plant's requirements.

Finish pruning climbers that require winter pruning, such as Stephanotis, Bougainvillea, Clerodendrons, Tacsonias, Bignonia venusta, Aristolochias, and Tecomas.

Hard-wooded Greenhouse Plants.—Many of the plants belonging to this section are very impatient of damp, either in the atmosphere (that is, when it is stagnant), or when water lodges on their leaves, such are the Aphelexis, Phacocoma, and many of the Ericas; therefore, ventilate freely on every favourable opportunity, using only just sufficient fire-heat to expel damp after watering. Place such plants where they can get as much light and air as possible. Encourage Acacias by giving abundance of water to which a little soot has been added. Now is a good time to repot and otherwise attend to that useful autumn flowering species, A. platyptera: it is just going out of flower, having lasted for about three months. A rather peaty loam with a good dash of sharp sand suits this plant best. Soft-wooded Heaths, such as hyemalis, caffra, gracilis, and autumnalis, which have done flowering, had better be cut back and placed in a warmer division, to encourage them to break; after which any potting considered necessary may be done. By thus giving them a longer season of growth, better results may be attained.

Epacris.—Many of those will at present be doing duty in the conservatory, and while mixed up among other plants they are apt to get over-watered, and

this is often the starting point of their decline. The *Epacris* does not require as large a quantity of water as most of the Heaths do, and there is this further difference, that Heaths should never be allowed to get so dry as *Epacris* before being watered—indeed, watering in this division requires a considerable amount of discrimination, and more so at this time of the year. It is sometimes rather difficult to make out whether the plants are dry or not; this might happen if the surface should appear dry, and the plants, through deficient drainage, should be wet at the bottom of the pot, or even the surface might be wet and the bottom dry through want of room between the top of the ball and the rim of the pot, thus preventing enough water being given at one time to soak the whole ball. These and kindred matters require looking to rather closely at the present time. Do not attempt what might be called a middle course by only giving as much as will carry over till tomorrow. At no time of the year than the present is it more imperative that plants be only watered when they require it, and then thoroughly. It is better to do with as little fire-heat as possible—40° as a minimum to 45° as a maximum—when the weather is mild.

Tuberous Plants: Gloxinias, Achimenes, and Caladiums.—Look over the stock and see that they are not getting too dry, and that the first and last named are not being kept too cool. A few of each might now be started, especially if it be desired to increase the stock of any particular kind. *Caladiums* are easily increased by taking off the growths close to the old tuber, so as to get a little heel; and if kept moist and warm they soon take root, if planted in tan or cocoa-nut fibre, and put under a handlight. *Frank Ross, Pendell Court Gardens, Bletchingly.*

THE FLOWER GARDEN.

LAWNS.—To render the surroundings as attractive as possible at this dull season, these should be kept scrupulously free from fallen sticks and leaves, and in mild open weather should be frequently rolled. When sufficiently mild the present time is good for laying turf, and for levelling and relaying turf on old lawns. Many lawns, after the trying heat and drought of last summer, will be greatly benefited by a heavy top-dressing of well-decayed manure and loam; this, of course, will present rather an unsightly appearance for a few weeks, and in some instances would be strongly objected to, especially if used in the immediate vicinity of the mansion. Under such circumstances, and where expense is not considered, apply as an alternative a top-dressing of bone-meal and superphosphate of lime, at the rate of half a peck to 30 square yards. Where lawns are in an unusually bad state, and much infested with moss, more thorough measures than the above should be adopted—sowing seed, and applying a dressing of lime, soot, and wood ashes; but this matter will be referred to later, when the time for sowing seed approaches. In the meantime, give the order to the seedsman for a renovating mixture, stating the character of the soil, the area of lawn, and at the same time stipulate for a liberal admixture of Crested Dogtail, Sheep's Fescue, and Smooth-stalked Meadow-grass.

Walks and Carriage Drives.—Put in repair and good order any drains that are defective, and clean out all catch-pits. Turn over gravel walks when practicable, and re-surface with fresh gravel where necessary, in doing so keeping them somewhat higher in the centre than at the sides, and roll frequently on favourable occasions so as to maintain a thoroughly firm and smooth surface.

Miscellaneous.—Examine *Dahlia* roots, tuberous-rooted *Begonias*, *Glaadiolus*, *Tigridias*, and cut out all decayed parts, afterwards dusting over the wounds with powdered charcoal, which will prevent decay going further. Pot imported bulbs of *Lilium auratum* for planting out at a later period, and place them in a cold frame plunged to the rims in loose cocoa-nut-fibre refuse, or cinder ashes, for a few weeks till they have made a start. *Roses.*—All beds and borders of these should ere this have been mulched with rich manure, and all *Tears* and *Noisettes* protected from frost with dry bracken. In open weather push forward the planting of *Box* edging and plant *Anemone coronaria*, *A. hortensis*, and their varieties; also *Ranunculus tuberosus*. These plants, which delight in a rich sandy loam, should be planted 3 inches deep and if the soil be at all poor, a liberal dressing of well-rooted cow manure and leaf-mould should be dug

in beneath the roots, and that is best done by bastard trenching the soil. Should there be a heavy fall of snow—which at the time of writing seems imminent—pay attention to *Conifers* and evergreen shrubs by relieving them of any undue weight on boughs and branches; men furnished with sticks wherewith to shake off the snow will prevent much wreck and ruin amongst these plants. *J. Horsfield, Heytesbury.*

THE HARDY FRUIT GARDEN.

COVERINGS FOR WALL TREES.—Various kinds of materials are recommended for the purpose of protecting trees from frost during the time they are in bloom, but of these *Frigi Domo* is generally conceded to be the best, and with proper care it will serve for several seasons. The old stock of it should now be examined, and repaired if that be found necessary. When temporary appliances are used in connection with the blinds, in the shape of wooden copings, the same should also be examined to ascertain if all is in readiness for use.

Winter Moth.—This pest has been present in great numbers this winter, therefore *Apple trees* (that were attacked with the caterpillar last year) should, after pruning, have the prunings carefully raked up and burnt, as by so doing a great number of the eggs laid by the female moth are destroyed. During *November* and *December* the females, which have only abortive wings, creep up the trees and lay their eggs on the leaf or flower-buds. In Germany, where the moth is more common than here, bands of paper smeared with a gummy substance or coal tar, are placed round the stems, and which, when kept in a moist condition, prevent the ascent of the female.

Top-dressing Garden Pear Tree Borders.—As these trees are generally grafted on the *Quince* stock, and are therefore surface-rooters, the soil about the roots soon becomes exhausted, and the trees in consequence of this show signs of exhaustion in the inferior fruit produced. When this is the case, the border should be top-dressed, at the same time removing a portion of the old soil to the depth of 8 or 9 inches. A suitable soil for the purpose is rich maiden loam, chopped up, with an addition of one-half its bulk of decomposed farmyard manure. This new material should be carefully worked in among the roots, laying them in at the same level they occupied in the old soil; then gradually fill up, and make the ground firm by treading it afterwards, and complete the operation by mulching heavily. Should the border be found to be in a very bad condition, the trees should be lifted entirely and replanted, but this is an operation that is better performed in the autumn. *A. Ward, Stoke Edith Gardens, Hereford.*

FRUITS UNDER GLASS.

PEACH HOUSES.—*Peaches* which are set may have the temperature raised to 55° at night in mild weather. The fruits which have set in clusters should be thinned to one fruit, always leaving the largest. If there is a good set all the fruits may be removed from the underside of the shoots, and the crop consist of those on the upper side, where they will have the full benefit of the sun, and be coloured on the top and sides instead of at the base. As soon as the wood-buds are sufficiently advanced disbudbing should be commenced, and this is better performed at several times: at the first remove all the buds from the front of the shoots, then those from the under side and back of the shoot, and lastly those from the upper side, leaving one only at the base of last year's shoot and a leader. If there be a vacant space to furnish, a shoot may be left at the base of this season's lead. No more shoots should be allowed to grow than are necessary to secure an evenly distributed crop of fruit. If the shoots are left too thickly the wood will be badly ripened, and which it will be necessary to cut out at the winter pruning, and the less these kinds of fruit trees are cut with the knife the better. Houses which contain trees in bloom should have a steady temperature of 50°, and the syringing be discontinued until the fruits are set. Go over the trees with a *Pampas-grass* plume about the middle of each day, and slightly draw the plume over the flowers. This is a more rapid and quite as effectual a mode of fertilisation as the camel-hair pencil. Get trees in later houses tied, and prepared for starting.

Pruning Young Trees.—Do not cut back young trees when planted, and any which were planted last season and have made strong growths should have such shoots left their full length, even if they should be 5 or 6 feet long; lateral shoots can be trained from the sides at distances of 6 to 8 inches apart to furnish the trellises and these will help to reduce the grossness of growth, as well as yield a crop of fruit the following season.

Figs.—Those which are intended to bring ripe fruits in April will be benefited by a bottom-heat of 75° to 80°—this is not absolutely necessary, but if it can be afforded them so much the better. Keep the roots in a moist state by waterings at a temperature of 85°. Let the temperature at night be as near 50° as possible, and when it reaches 65° by day admit a little air; syringe the trees in the morning and afternoon of fine days. Clean and dress succession plants, being careful not to pot any plants at this advanced season: have recourse to rich top-dressings and feeding with manure-water instead.

Strawberries.—Plants which are swelling should be well syringed, and a temperature of 60° to 65° may be kept up at night. Alternate waterings with clear soot-water and weak guano may be given. Wire shelves are best for holding *Strawberries* in pots, as they allow of the plants being syringed all over and underneath, which is a great matter with plants so liable to red-spider as these. Plants in bloom may have the temperature advanced to 55°, but do not syringe while they are in bloom. The weaker bloom-buds may be picked off if the trusses be large. If the weather be dull, go over the flowers with a camel-hair brush in the middle of the day. Put in a fresh stock of plants every eight or ten days, according to convenience or requirements. Examine each pot for worms, and see that the drainage is all right. The *Strawberry* is a moisture-loving plant, but it will speedily show its distaste for stagnant water at the root. Do not let the temperature for starting successive batches exceed 45° at this season. *W. M. Baillie, Luton Ho.*

THE KITCHEN GARDEN.

PEAS that were sown in *November* will now require protection from frost, a good dressing of coal-ashes or sawdust being first spread along the rows to check the ravages of snails. After repeated trials I prefer coal-ashes for this purpose; sawdust (although being more effectual against snails) holds the moisture too much, and if the weather be very severe the *Peas* suffer accordingly. The stalks may afterwards be put in, and then some boughs of *Spruce* or other evergreens placed along the sides. It is well, if room can be spared, to sow some of the early kinds now, either in strips of turf or in small pots. The turf for this purpose requires to be cut and stored in the autumn, and should consist of pieces 9 inches long by 3 inches wide and 2 inches thick. Make a small groove down the centre, sow the *Peas*, and cover them with some good soil. If turf is not at hand, put five seeds in large 60's. After sowing, the turves or pots should be placed in a temperature of 45° to 50°, and if well hardened off before planting out they will be ready for use as soon as those sown in *November*. *Broad Beans* may also be treated in the same way.

Any *Asparagus* beds that show exhaustion should be dug up, and the roots placed in a hotbed frame on fermenting material, with a bottom-heat of not more than 80°.

As soon as the produce of a row or bed of *Seakale* or *Rhubarb* is cut, remove the fermenting material; trim the stools of the former, and cover both with rough leaf-soil or short straw, as a protection against frost. The thongs or small roots of *Seakale* that has been taken up for forcing purposes should be cut into pieces 2 inches in length, the upper end being cut square across and the lower slantingly, and be put thickly in pans or boxes of soil, and placed where they are safe from frost until planting time arrives. *W. H. Divers, Kilton Hall.*

PUBLICATIONS RECEIVED.—*National Footpath Preservation Society's Third Annual Report*. (London: 52, Essex Street, Strand, W.C.)—*Annual Administration Report of the Forest Department, Madras Presidency, for 1885-1886*. (Madras: R. Hill, Government Press.)

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

WEDNESDAY,	JAN. 25	{ Roses, Fruit Trees, Shrubs, Border Plants, &c., at Stevens' Rooms. Japanese Lilies and other Bulbs, at Protheroe & Morris' Rooms.
THURSDAY,	JAN. 26	{ Imported Orchids, from Mr. F. Sander, at Stevens' Rooms.
FRIDAY,	JAN. 27	{ 2000 Odontoglossum crispum, and other Orchids, at Protheroe & Morris' Rooms.
SATURDAY,	JAN. 28	{ Roses, Fruit Trees, Shrubs, Border Plants, &c., at Stevens' Rooms. Bulbs and Plants, at Protheroe & Morris' Rooms.

The Gardeners' Royal Benevolent Institution.

It is refreshing to have to advert to the affairs of this Institution, which are as satisfactory and hopeful as some others to which we have had to advert are the reverse. At the annual meeting, held on Friday, 13th inst., the usual resolutions as to the adoption of the report and balance-sheet were passed. Mr. Harry Veitch was re-elected Treasurer, Messrs. John Lee, Meston, and Willard as Auditors, Messrs. E. Tidswell, Jas. Webber, E. W. Cathie, G. Monro, and W. Richards as Arbitrators, and Mr. Cutler Secretary for the forty-seventh time. New members of the committee were elected in the persons of Messrs. N. Sherwood (Hurst & Sons), Roberts, Gunnersbury; J. Laing, Forest Hill; A. F. Barron, Chiswick; G. Woodgate, of Kingston; and H. Tillman, of Covent Garden. Three persons, viz., Elizabeth George, Patrick John Hanafy, Caroline McElroy, were placed on the list of pensioners, without the necessity of election, they (or their husbands) having subscribed to the Society for the specified period; and in addition to these and five others selected by the committee, four others, the next highest on the poll, were elected to fill the vacancies which had occurred since the voting papers were issued, the names of those elected being Thomas M. Wall, Matilda Charlton, Charles Pepworth, James Ewing, William H. Head, Elizabeth Horton, Henry Moxham, Francis Fuller, and Mary Nelson.

The usual votes of thanks were passed to the President of the Festival on June 29 last, and to the officers. The following is the text of the Report; the balance-sheet was published in our last issue:—

"It is with infinite satisfaction that the committee present their report for the year 1887, and they sincerely congratulate the subscribers on the great success that has attended their labours during that time.

"During the year fourteen pensioners have died, five leaving widows, and these having been found worthy, and having in every way complied with the rules, were, in accordance with Rule No. 7, placed on the pension list in succession to their late husbands.

"This being the year of Her Most Gracious Majesty's Jubilee, it was after very mature deliberation determined by the committee that some steps should be taken to mark that auspicious event, and it was eventually arranged that a special Jubilee grant of £5 should be made to each of the pensioners, and to each unsuccessful candidate at the last election, and that a special appeal for this object should be made

mittee have to announce that the Right Hon. JOSEPH CHAMBERLAIN, M.P., has most kindly consented to succeed Baron FERDINAND DE ROTHSCHILD as Chairman at the festival to be held in the ensuing summer, and they have reason to believe that, with such a distinguished President, the festival will be a grand success. The number of pensioners on the list is 114, to be this day increased to 126."

At the dinner in the evening a large number of subscribers and friends sat down, with the Right Hon. Sir ROBERT PEEL, Bart., in the chair, supported by Messrs. John Lee, N. Sherwood, Dr. Hogg, J. Veitch (Treasurer), T. F. Peacock (Hon. Solicitor), E. R. Cutler (Secretary), and others.

The Chairman remarked that it was with much pleasure that he was present on this occasion, and referred to the beneficent influence of horticulture, finally inviting anyone interested in the art to visit his gardens at Tamworth Court.

Mr. H. VEITCH, the Treasurer, in the course of his remarks, contrasted the present flourishing

Warszewiczii*; 8, *S. marginatum*; 9, *Cineraria platanifolia* (*S. petasites*); 10, *Solanum glutinosum*; 11, *S. atropurpureum*; 12, *McIlhenny major*; 13, *Entelea aborea*; 14, *Amicia zygomeris*; 15, *Solanum minusmosum*; 16, *Senecio Ghiesbreghtii*; 17, *Urtica bipinnatifida*.—a, *Iris sine Hovey* (1 ring); b, *Veronica Andersoni* (1 ring); c, *Antennaria tomentosa*; d, *Festuca glauca*; e, *Lobelia fulgens* Queen Victoria; f, *Anemone japonica* Honorine Jobert; g, *Alternanthera atropurpurea*.

to the public and the horticultural world. This appeal, your committee are pleased to say, was nobly responded to, more particularly by gardeners, to whom special collecting-cards were issued, resulting in a clear sum of £677 12s. 2d.; this, with the donations, &c., received at the annual festival, have enabled the committee, not only to pay the largest amount ever distributed in pensions—viz., £2124 10s.—but also to make the proposed Jubilee grant, amounting to £635, without trenching upon the reserve fund.

"This has been with one exception the most successful year on record, and the committee have to return their best thanks and acknowledgments to Baron FERDINAND DE ROTHSCHILD, M.P., who so kindly presided at the forty-fourth anniversary festival on June 29 last, who, by his influence and his eloquence, added to his liberality and that of his friends, so materially assisted in securing a very large subscription list, and making the festival one of the events of the season.

"It is with infinite satisfaction that the com-

condition of the affairs of the Institution with what the condition was in former years, showing a steady and remarkable increase of revenue, a diminution of working expenses, and, what was still more satisfactory, an increased number of pensioners, stating that he hoped that in a few more years the income of the Institution would be such that all the applicants could be placed on the pension list without election.

Dr. R. HOGG said that, as far as he was concerned, he would do all in his power in the Press to advance the Institution, and was certain that other members of the Press would not be behindhand in furthering the interests of the Institution.

With this bare outline we close our notice of an Institution which is obviously well managed, which effects a great amount of good, which is thoroughly worthy of the support of the fraternity, and which is likely to be even more useful in the future than it has been in the past. For

the great success it has achieved—its steady progress from the lowest point to its present sound financial condition—the thanks of the community are due to Mr. E. R. CUTLER, who, as we have said, for the forty-seventh time was elected as its Secretary.

DAFFODILS.—*On commence.* Mr. HARTLAND begins. He sends us flowers of his Ard Righ Daffodil, and also of the white Narcissus moschatius, grown in a cold frame and in a cold house respectively.

the flatter, flaccid, recurved pale green unbordered leaves, with fissured tips at an early age, and which are rolled back so that their tips reach or lay on the ground. It grows pendulous from the rocks along the Waitangi River in great abundance. The plant figured flowered at Torquay in the garden of Dr. LOMBE.

Ceratotheca triloba, t. 6974.—A beautiful stove herb, with racemes of Paulonia-like flowers. See *Gard. Chron.*, 1887, p. 492, fig. 99.

Thunbergia affinis, t. 6975.—A beautiful erect stove shrub, with large funnel-shaped flowers, with a curved tube, a purple five-lobed limb, with a yellow

inches broad, are so placed that the lip is uppermost. The three sepals are equal, ovate-roundish, green spotted with purple, and each prolonged at the apex into a long slender tail, lip with a curved stalk, and a rounded two-lobed hooded anterior lobe of an orange colour, with purple radiating lines on the inner surface.

HANDBOOK OF THE AMARYLLIDÆ.—We are pleased to learn that Mr. J. G. BAKER'S *Handbook of the Amaryllidæ* is in a forward state of preparation, and will be ready for publication in the course of a few weeks. It will be a cheap working hand-

FIG. 14.—GROUP OF FOLIAGE PLANTS AT WILHELMSHÖHE. (SEE P. 83.)

ORCHID CATALOGUE.—We have received a copy of the catalogue of Orchids cultivated in the Botanic Garden, Leyden, by Mr. H. WITTE, who prepared a similar catalogue in 1862. The present issue contains no fewer than 720 entries, it would have been interesting to have noted how many were included in the list published in 1862. Synonyms and references to books and plates are given, so that the book will, in spite of the proofs having been here and there imperfectly read, prove very serviceable.

"BOTANICAL MAGAZINE."—The January number opens with a coloured illustration of a new species of New Zealand Flax, called *Phormium Hookeri*, t. 6973, differing from other species "in

throat. See *Gard. Chron.*, ser. 3, vol. ii., 1887, p. 460, fig. 94.

Prunus Jacquemonti, Hook. f., t. 6976.—A low growing shrub, recalling the old *Amygdalus nana*, with ovate lanceolate finely toothed leaves and small Peach-like flowers arranged in clusters along the sides of the branches. It is a native of north-west Himalaya and Afghanistan. Seed were sent from the latter country by Dr. ARNISON to Kew, where the plant flowered in May, 1887, the leaves not being fully developed till the following July.

Masdevallia Chestertonii, Rehb. f. (*Gardeners' Chronicle*, vol. xix., 1883, p. 532), t. 6977.—A curious New Granadan species, with pendulous slender one-flowered peduncles. The flowers are about 2 2½

book of genera and species on the plan of HOOKER and BAKER'S *Species Filicium*, and his *Handbook of the Fern Allies*, published a year ago. It will, of course, contain a revised version brought up to the present time, of his synopses of *Narcissus*, *Criinum*, *Nerine*, *Agave* and *Fouquieria*, which have appeared in our columns, but exclusive of the *Hypoxidææ*. Sixty genera, and nearly 700 species of the order are now known, of these 500 have been brought in cultivation, although a good many have not become permanently established as garden plants.

THE PRICE OF POTATOS.—From a trade list just to hand we are able to gather some information as to the prices of seed Potatos. Taking into con-

sideration the fact that the crops of early varieties were light, they are yet extraordinarily cheap in price. *Magnum Bonum* is quoted at £3 per ton, or 3s. per cwt., and it seems difficult to realise that they can be grown and sold at such a low price, and yet made to pay. Other leading sorts, such as *Reading Russet*, *Schoolmaster*, *Myatt's Prolific*, *Early Regent*, *Climax*, *Imperator*, and *Reading Hero*, are cheap in proportion, and we are almost at the commencement, instead of being at the close of the season.

THE ROYAL HORTICULTURAL SOCIETY.—The following are the names of Fellows nominated for the Council at the ensuing annual meeting on February 14, when all the members of the Council will resign, but when it is proposed by the Council that certain members be thereafter re-elected and other new ones added. We understand that objections are likely to be raised to some of these proposals:—*Sir Trevor Lawrence, Bart, M.P.*; *Robert Hogg, L.L.D., F.L.S.*; *Professor M. Foster, F.R.S.*; *D. Morris, M.A., F.L.S.*; *W. T. Thiselton Dyer, C.M.G., F.R.S.*; *A. H. Snee, William Lee, Col. Beddome, George Paul, Harry J. Veitch, Sydney Courtald, E. G. Loder, Rev. W. Wilks, Baron Henry Schroder, and G. F. Wilson, F.R.S.* Messrs *Morris, Snee, Paul, Veitch, and Wilks* are proposed to take the places of *Major Mason, Mr. W. Haughton, Hon. and Rev. J. T. Boscaen, Col. Trevor Clarke, and G. Maw.* As officers the Council recommend the following:—*President, Sir Trevor Lawrence, Bart, M.P.*; *Treasurer, D. Morris*; *Secretary, W. Lee*; and *Auditors, Messrs. John Lee, Wm. Richards, and H. Turner.*

PORTSMOUTH CHRYSANTHEMUM SOCIETY.—The annual dinner took place at the Royal Albany Hotel on Friday, January 13, F. Power, Esq., the Secretary presiding, the vice-chair being occupied by W. G. Ellis, Esq. Amongst the successful growers of the Chrysanthemum present were Messrs. *KIMBER, COLLINS, MOLYNEUX, DROVER, &c.* The loyal toasts having been duly honoured, *Sir W. King* proposed the toast of the evening, "Success to the Portsmouth Chrysanthemum Show." He stated this was the third dinner he had attended, and what pleasure it afforded him to briefly notify how each season had been more successful than its predecessor, for though the society had given nearly £130 in prizes at its last show, yet they still had a balance of £121 15s. *Id.* He was pleased to learn that the committee thought of keeping the next show open for three days. The Chairman, in responding, said they had received the support of some of the very best growers in England, such as Messrs. *MOLYNEUX* and *DROVER.* Messrs. *MOLYNEUX* and *DROVER* responded on behalf of the growers, the former remarking he feared that the three days would be a mistake; however, that was for the committee to decide, and suggested the offering of a prize less in value than the Cup, but higher than any money prize the Society has hitherto offered. *Mr. Drover* coincided with *Mr. Molyneux's* views, advocating the holding of a show the week before Christmas.

DRYING FLOWERS IN THEIR NATURAL COLOURS.—*Dr. Schönland* kindly sends us the following details of his system of drying flowers:—"Take two pints of a saturated solution of sulphurous acid in water (which can be had at any chemist's, and is very cheap if bought in large quantities); add to this 1 pint of methylated spirit. Keep this mixture in a wide-mouthed bottle, which should be so tightly closed that the contents do not evaporate when not in use. Leave ordinary flowers in this mixture for about ten to twenty minutes; inflorescences of *Bromeliaceae* and *Aroideaceae* must be left in it about one hour. In most cases the colour will completely disappear, but it will gradually return during the process of drying, or even after the plants have become apparently quite dry. Having treated the specimens with the mixture for a short time, as stated above, take them out, and shake off the adhering drops of fluid. Leave the

plants in a dry, warm place, in order to dry them superficially (they must not be allowed to shrivel), and then dry them in the usual way between blotting-paper. If artificial heat is used in the latter part of the process excellent results are obtained; and it is not even necessary to change the drying-paper. If hot-water-pipes are available, it is very convenient to place on them the bundles containing the plants to be dried, which need not be subjected to very great pressure. As it is sometimes difficult to prevent flowers from collapsing, when using this method of preservation, and as often, it is almost impossible to spread out those flowers when they have collapsed, I often put them loosely between sheets of vegetable parchment before immersing them in the fluid."

BANBURY CHRYSANTHEMUM SOCIETY.—This Society has suffered a great loss through the death of its highly popular and able young secretary, *Mr. F. G. Day*, after a very short illness. *Mr. Day*, who was connected with a firm of solicitors in the town, brought to the discharge of his secretarial duties business qualifications of a high order, and his death is a very serious loss to the Society.

M. Deherain has been elected into the Academy of Sciences—section of Rural Economy.

BRIGHTON AND HOVE CHRYSANTHEMUM SHOWS.—The dates for the above shows are fixed for November 13 and 14, and it may interest the many intending exhibitors among our readers to learn that the schedules will be ready by the first week in March, and may be then obtained from the Secretary, *Mr. M. Loxton*.

PREPARING ORCHIDS FOR THE HERBARIUM.—Several methods for preparing Orchids for the herbarium so as to preserve their colours have been tried by *R. Hebler*, and the results given in the *Deutsche Botanische Monatschrift.* Salicylic acid was used with good success by dusting the dry substance upon the plants as they lie in the press. When they are taken out of the press the salicylic acid is removed from the flowers with a brush, and can be used for other plants. It specially preserves the intensity of the red colours. Powdered boracic acid may be used in the same way with nearly as good results. A solution of one part salicylic acid to fourteen parts of alcohol, applied by moistening pieces of blotting-paper and placing them above and below the flowers in the press, or by wetting absorbent cotton and putting it in and about the flowers, forms a simple method of attaining the same end.

OXFORDSHIRE CHRYSANTHEMUM SOCIETY.—The annual exhibition of this Society is fixed for November 20. Last year the income of the Society was less than its expenses, owing to various causes, but generally the shows prove financially successful.

LIGHT AND FLOWERS.—According to a paragraph in the *Journal of the Royal Microscopical Society*, *Professor Sachs* has been experimenting on the action of the invisible rays of the spectrum beyond the violet. The experiments were made on the common *Nasturtium* (*Tropaeolum majus*), which was made to grow behind a glass vessel or screen filled with a solution of sulphate of quinine which absorbs the ultra violet rays, *i.e.*, does not allow them to pass or transforms them into visible rays of less refrangibility of a light blue colour. The effect of so growing a plant exposed to light passing through a solution of sulphate of quinine was to develop the foliage inordinately and entirely to check the production of flowers. The experiments were numerous and compared with others where the light was suffered to pass through water in which latter case flowers were abundantly produced. It may then be assumed there are three distinct regions of the solar spectrum differing in their physiological action: the yellow rays which favour the decomposition of carbon dioxide and are active in assimilation; the

blue and violet rays, which are the agents in the movements of vegetation; and the invisible ultra violet rays, which cause the production in green leaves of the substances out of which flowers are developed. These are laboratory experiments, but it is quite conceivable that they might be turned to account by practitioners. Suppose, for instance, it were desired to retard the flowering of a particular plant, grow it for a time in the shade, so to speak, of a solution of sulphate of quinine! Seriously, we greatly stand in need of such experiments to set us thinking and acting in the future.

THE ARAUCARIA OF NEW GUINEA.—Among the plants of striking interest, observed by Messrs. *CURRIER* and *SAYER* during their ascent of Mount Obree, writes *Baron von Mueller*, one of the foremost is a coniferous tall tree, occupying rocky declivities at elevations from 6000 feet upwards. The careful examination of a fruit-bearing branchlet reveals the identity of this "Pine" with the *Araucaria Cunninghamii* of tropical and sub-tropical Eastern Australia, so well known in Europe as one of the noblest of conservatory trees. *Dr. Beccari*, when ascending Mount Arfak in Dutch New Guinea in 1877 came across the same *Araucaria*, which he likewise pronounced as not distinct from *A. Cunninghamii*; but he noticed it at heights from about 3900—4900 feet, though the Italian explorer reached an altitude of fully 6000 feet. The occurrence of this *Araucaria*, on mountains so very widely apart in the great Papuan island, seems to indicate that much of the highland country there is likely occupied by this Pine, which fact—if it could be established—would be of geological significance and otherwise also be of physiographic importance. *Professor David Don*, so long ago as 1838 (*Trans. Linn. Soc., Lond., xviii., 164*) considered it not improbable "that the interior of New Guinea might afford a species of *Araucaria*," an anticipation now realised. *Mr. Sayer* found the branchlets less vaguely spreading and more distichous than in the ordinary state of this tree in Australia. The *Araucaria Balansæ* from New Caledonia is closely akin to *A. Cunninghamii*, as characterised in Australia and New Guinea. Here it may aptly further be noted, that *Araucaria Rulei* was first described in the *Gardeners' Chronicle* for 1861, when a woodcut of the typical form was given.

THEN AND NOW.—A correspondent writes: "Just 101 years ago the *Botanical Magazine*, 'printed for W. Curtis, at his Botanic Garden, Lambeth Marsh, 1787,' gave an illustration of *Cyclamen persicum* of *Miller*, and it is represented by a white flower with a rose-coloured rim to the corolla, the segments being long and thin, the widest not half an inch in diameter, and representing the very worst type of the flower that could, perhaps, be found in a very bad strain of the present day. On the last day of the year we saw a batch of *Giant White Cyclamen*, a very fine pure white type, of great beauty and purity; and on spreading out the segments from the mouth of the corolla it was found the measurement from tip to tip was something over 4 inches, and the diameter of the segments quite an inch, and yet the freedom of bloom was as great as in the case of one of the commonest forms of the *C. persicum* type. Here, then, was a conspicuous example of the remarkable advance made in the case of the *Persian Cyclamen*; and not only have the flowers become greatly enlarged and refined, but our methods of culture are very different to what they were at a much less remote period; and now it is possible to sow the seeds in November of one year, and in the same month of the following year to have a fine plant carrying from twenty-five to fifty blossoms!"

MIDLAND INSTITUTE, BIRMINGHAM.—The following is the programme of lectures to be given at the Society's room, at 7.30 o'clock, on Tuesday evenings during the season:—January 17: "Florists and Florist's Flowers," by *Mr. J. Pore.* General discussion on the same to follow. January 31: "Flower Gardening," by *Mr. W. Wilks*, *Heckfield Place, Hants.* February 14: "Alpine Plants, their Natural

Habitats and Cultivation," by Mr. G. GURME. February 28: "Medicinal Plants and the Drugs we get from them," by Mr. A. E. ROBINSON. March 13: "Cultivation of Fruit Trees in Orchard-houses," by Mr. T. F. RIVERS, Sawbridgeworth, Herts. March 27: Reading of prize essays, and awarding of the prizes. The following prizes are offered for essays or papers; intending competitors to send in their papers to the Secretary, by post only, not later than March 17, such papers to bear a private mark or motto only; in no case must they bear the name of the competitor, or occupy more than ten minutes in reading. One person will be appointed to read the whole of the papers before the committee prior to the general meeting on March 27, when the successful papers will be read and the prizes awarded:—Single-handed Gardeners where no permanent help is given: The best twenty-four most useful plants for keeping the conservatory gay during the twelve months, with notes on their culture and time of flowering. First prize, 10s.; second prize, 5s.; third prize, 2s. 6d. Under-Gardeners: Twenty most useful herbaceous plants, with notes on their propagation and cultivation. First prize, 10s.; second prize, 5s.; third prize, 2s. 6d.

M. BALTET.—This well-known horticulturist has lately been appointed (as we learn from *Le Jardin*) Chevalier of the Legion of Honour.

LICHENS.—It will be known to many of our readers that of late years some botanists have come to look on lichens, not as distinct plants, but as associations of an Alga, or green plant, with a colourless fungus feeding upon it and keeping it within bounds, but not, as it seems, destroying it utterly. It is not wonderful that this explanation should be thought fanciful and incorrect, and the view is still warmly contested by those who study lichens from the systematic side only. Evidence, however, from various quarters concurs in showing that the notion, however strange it may appear, is correct. The first fungus detected belonged to the group Ascomycetes, in which the spores are produced in special sacs or cells, called asci. A few years since an Italian botanist followed up the subject by demonstrating the existence of a second type of lichen-structure characterised by the production of spores on cellular stalks, or "basidia," which latter are compacted together into a continuous mass, as in the hymenomycetous fungi (e.g., Agaricus). In a recent number of the *Philosophical Transactions* Mr. MASSEE refers the curious Emericella of BERKELEY to a new type of lichen, which he calls Gastero-lichenes, inasmuch as it consists, according to him, of a fungus of the order Trichogasteres in association with an Alga called Palmella botryoides. BERKELEY seems to have narrowly anticipated SCHWENDENER's views.

A GROUP OF FOLIAGE PLANTS.

The arrangement of the materials in the fine bed of foliage plants shown in figs. 13 and 14, for sending which our thanks are due to Mr. Karl Gotze, display variations from the methods usually adopted in English gardens. We will let Mr. Gotze describe them:—

The bed in question was several years ago laid out in the Royal gardens of Wilhelmshöhe, near Cassel, which is one of the many interesting and splendid spots in Germany. In former times Wilhelmshöhe was the favourite castle of the late Kurfürsten van Hessen, and since the Franco-German War it is well known as having been the place of captivity of Napoleon III.—a splendid imprisonment! The royal garden and parks, which are under the management of the Hofgartner Franz Vetter, are open to the public daily, and thousands of visitors from all parts of the world come every year to visit the place.

The bed illustrated, measured about 34 feet in length, and 22 feet in the broadest part. The centre of the bed was filled with different foliage plants edged with a couple of lines, one of *Fesine Hoveyi* (a), the other of *Veronica Andersoni* (b). About

5 feet space was given for the broad edging (c), laid out with the white *Antennaria tomentosa*, whilst the circles were planted with the brilliant *Lobelia fulgens* var. *Queen Victoria* (e), the more or less square spaces alternating with the circles with the beautiful white flowering *Anemone japonica* *Honorine Jobert* (f)—both the *Lobelia* and *Anemone* patches being edged with a single line of the useful *Festuca glauca* (d). An outside edging to the whole consisted of two lines of the dark red *Alternanthera atropurpurea* (g). I was much struck with the appearance of the bed when I saw it, and, indeed, I doubt if any better way of displaying foliage plants could be found than is now represented.

The edgings of *Antennaria*, *Lobelia*, and *Anemone* were capital ideas, and contrasted well with the masses of the foliage plants. *Karl Gotze, Kensington.*

THE BULB GARDEN.

FREESIA CULTURE.

It is not an easy matter to assign any particular reason to the query of your correspondent, "R. H. L.," p. 52, as to why his *Freesias* "have not grown;" especially is this the case after careful reading of the note in question. "R. H. L." has evidently followed a good cultural routine generally, but is he sure of a perfect maturation of the bulbs after flowering last year?—for in this lies much of the secret of their successful culture; therefore, to have them continuously good year by year it is essential that a gradual yet thorough ripening of the bulbs be annually adhered to. From the report of your correspondent the bulbs are of good size and sound, therefore it is the more vexing that they do not start into growth. Since the bulbs in question appear to have been bought in 1886 it is not unlikely that these were imported ones, which usually flower freely in the first year, while many in the second year remain dormant, starting into growth the following autumn as though they had only taken their usual rest; this is particularly noticeable with small bulbs, and less frequently with large or what may be termed in the trade flowering bulbs. In one case in particular in my experience several hundreds of small bulbs remained dormant fully a year; these were the refuse from a large importation a year previous, while another batch of newly imported ones came up as thick as a bed of spring Onions in three weeks, and this after a prolonged rest. I do not think your correspondent acted wisely in placing them in a cool place after they had finished blooming. Why not have matured and dried them off under the same conditions where they "grew and bloomed to perfection?" It is not unlikely that thus placing them in a cooler place at the very moment when they needed the warmth as much as ever, has a deal to do with their partial failure this year. Certainly such a course is quite foreign to their nature, while it is freely given to plants of a more enduring and indifferent constitution with impunity. I should certainly never advocate such a course of treatment for the more fragile subjects, and the *Freesias* among their number. Generally their cultivation is not widely known—a fact much to be regretted, for they are beyond doubt among the most exquisite of fragrant flowers. The soil I prefer is equal parts of peat and fibrous loam, made very sandy, a free and abundant drainage, water sparingly at all times, with a thorough gradual ripening process. They appear quite indifferent as to how long they are kept dry, by which I mean to say, that bulbs may be planted in the present month (January) with as much success as those planted in October, with the additional advantage of making a long season of bloom. It does not appear that your correspondent has subjected his bulbs to excessive heat, or the failure might be attributed to this.

In conclusion, I am inclined to the belief that if your correspondent will (as I do) give his bulbs a thorough baking in full sun for six weeks, or there-

abouts, without water near them, and be content with starting them in October, he will be more successful than by his present method of preserving them in the seed cupboard, for in this place they lose absolutely what *Freesias*, *Ixias*, and such-like appear to enjoy, viz., sun, and which is so conducive to their well-being. *E. Jenkins.*

CULTURAL MEMORANDA.

ERANTHEMUM PULCHELLUM.

This pretty blue-flowering stove plant is not so frequently met with in gardens as it used to be, and deserves to be still. It is of very easy culture. Cuttings taken off now, and inserted singly in 3-inch pots, filled with an admixture of light sandy loam and peat or leaf-mould, watered and placed in heat, will soon take root. These, by judicious pinching and shifting into 4½-inch and 6-inch pots at intervals, as they require more room at the roots, and by keeping the latter sufficiently moist, will make nice bushy plants by next autumn. Well-flowered plants of this *Eranthemum*, *Eucharis amazonica*, and scarlet-flowered *Begonias*, intermixed with Ferns, are very effective, whether arranged in groups in the house, or on the stages in the stove and conservatory. *Eranthemum igneum*, a stove plant, with handsome bronze foliage, for which it is chiefly valued, can be propagated at the same time, and in the same way.

CAMELLIAS.

These do well in a minimum temperature ranging between 45° and 50°, giving the plants 5° more by day with fire-heat, and running it up to 75° with sun-heat. When the soil has become moderately dry in the tubs and pots water should be given, and in the case of very well rooted plants liquid manure may occasionally be afforded them. Plants in borders will require but little water at this season, unless they are very small and shallow ones, filled with the roots of the plants. In that case great care must be taken to prevent flagging, which would be followed by the loss of the greater number of the flower-buds. This loss of the buds will sometimes occur when a plant stands too near the heating apparatus when hard driven in severe weather. Soot-water is a useful stimulant for the *Camellia*. *H. W. W.*

FLORISTS' FLOWERS.

PLANTS IN FRAMES.

No sooner do we enter into the new year than active operations are required amongst these interesting occupants of our gardens. If the weather is favourable there is much to be done out-of-doors amongst the flower beds and borders, and in mild weather the occupants of frames can be overhauled, *Auriculas*, *Primulas*, *Carnations* and *Picotees* examined for insects, and to remove weeds or any parasitical growths from the pots and from the frames. Cleanliness is absolutely necessary for the health and vigour of plants. Efficient ventilation is also of much importance. I have seen the frames of these hardy flowers closely shut up in cold dry weather, when it would have been much better to have had the lights drawn off altogether. Plenty of dry air is the life of the plants at mid-winter. Shut up in foggy and wet muggy weather.

The plants of the show varieties in frames are looking well, and if they are to be placed in a house must be attended to very soon—not later than February 1, at any rate. If the house has had other occupants, and these are removed, the glass and woodwork must be cleaned, and the pots washed, and the plants themselves made clean. Excepting greenfly and the woolly aphis, no other insect troubles the *Auricula*; but as the one attacks the leaves while the other is paying attention to the roots, it may be supposed to be enough. Any of the

woolly apsis that may be upon the necks of the plants should be removed, and some fresh compost pressed round in place of the old. If the weather be mild the seedling plants will push into growth even more rapidly than the others, and require to be potted on; the largest plants may be ready to be planted in small pots, and the tiny ones, with, perhaps, only one leaf besides the seed-leaves, are pricked out also in small pots, but from six to a dozen in each, according to their size. The compost for these must be of a lighter and more sandy nature than that used for large plants.

AUBICULAS OUT-OF-DOORS.

These have succeeded admirably during the winter, and they now look quite green, with the hearts round and firm; the few large outer leaves have quite decayed, and must be now removed, at the same time pressing in the plants with the fingers if necessary. I like to leave the soil round the plants undisturbed, merely removing the weeds, and leaving any green moss to remain, as the plants have a much more charming effect amongst moss, that is, if it is naturally grown.

The plants succeed best in positions where water drains away quickly, if the soil is of a medium or even heavy clay I find they do not mind exposure to the sun; of course, they must not be dried up by want of water, as well as much heat, in summer. *J. Douglas.*

CHRYSANTHEMUM GOLDEN GEM.

Those of my brother gardeners who have not yet added this variety to their stock should not fail to obtain it. For the embellishment of the conservatory and house throughout January it will be found very valuable, being robust, of dwarf habit, with that good quality of retaining its foliage well up to the season of its flowering. All those who have grown it are indebted to Mr. Owen, The Floral Nursery, Maidenhead, for a valuable addition to winter flowering varieties. *H. Vickery, Huntsmoor Park, Iver.*

FORESTRY.

Prompt attention is required when snow falls to prevent the destruction of the branches of evergreen trees and shrubs, and to do so effectually long and light poles should be provided, and if these are provided with a hook at one end so much the better, and placed in the hands of careful workmen. Every tree and shrub, it may be well to say, will not require to be divested of the accumulated snow on the branches, but only such as from their weighed-down appearance show that they are in danger of being broken; indeed, no better covering than a mantle of snow could be afforded.

Here it may be well to inform the "snow-shakers," but particularly those of the thoughtless caste, that "the last straw breaks the camel's back," and so it is with the snow-laden branch, for unless it be carefully divested of its burden, evil and not good is sometimes the result; therefore, never clasp the branch with the hook and pull downwards, but gently shake it from side to side, and afterwards in any way that may be found most convenient. If there is a specimen, be it big or small, of that lovely Conifer, *Cryptomeria elegans*, in the ground, give it first attention, for it gets badly broken by heavy snowfalls. Amongst shrubs the Yew and Box, as well as the *Laurustinus* and *Escallonia*, will require early attention during or immediately after a fall of snow, but being of low stature their wants are by no means difficult to attend to. In the nursery, too, we have often found it necessary to send a few men round with short sticks to shake the snow from off the more brittle-wooded and dense-foliaged plants, as well as to pay particular attention to those that have been recently grafted, as even a small weight of snow on the scion may cause it to become detached from the stock, and so a season's growth is lost. Indeed, a general look round the park woods and nursery immediately after, or even during a heavy and still falling snowstorm, is time well spent. *A. D. Webster.*

USEFUL INVENTIONS.

THE MYTICUTTAL.

UNDER this rather odd title the Standard Manufacturing Company of Derby have introduced a form of pruning-knife suitable for pruning shrubs, hedges, Rose bushes, and the like. So far as the cutting

FIG. 15.—THE "MYTICUTTAL."

part is concerned, the new instrument is substantially the same as the "Standard Tree-pruner" sent out by the same firm some years ago, but the knife is moved by a slide, which works up and down the shaft, and is itself moved by two levers, by pressing which the cut is easily and swiftly performed. We have had considerable experience with the "Standard Tree-pruner," which does its work so easily and so well, that we were prepossessed in favour of the smaller tool, in a way that we should not have been by the mere inspection of

the implement when not in use. We can imagine any one looking askance at these weapons, but only let him see them at work—or, better still, use them himself—and he will be, as we were, as much delighted as surprised. This having been our experience with the tree-pruner, we lost no time in trying the "Myticuttal," when something of the old feeling of surprise came over us at the great power of the instrument, the ease and comfort with which it can be used, and the excellent way in which the work is done. In spite of frequent and often rough usage during two or three years, the Standard Tree-pruner has never needed repair or even sharpening, so that if the Myticuttal should prove, as we believe it will, to possess the good qualities of the parent, a boon will be placed in the hands of the workman of no ordinary nature.

ERIOSTEMON OBOVALIS *fl. pl.*

ONCE upon a time it was stated that there were no double flowers in Australia, then that they were rare, then that they only existed in cultivated plants, and that Australia was young in cultural matters, therefore there was a scarcity of double flowers. Most of these propositions have been overthrown by the progress of discovery, so that now-a-days it would be easy to find acceptance for the belief that the proportion of wild double flowers is about the same in Australia as anywhere else. Be this as it may Baron von Mueller has lately sent us flowers of an *Eriostemon* bearing numerous double flowers towards the ends of the branches. This plant would make a very pretty greenhouse plant, but it would of necessity have to be propagated by cuttings, as it could not produce seed. As cuttings form, however, the usual method of propagation, this defect is of no moment. The flowers are doubled by the multiplication of the petals and by the development of the stamens in spiral lines along the prolonged thalamus. To those conversant with the conformation of *Rutaceæ* these structural peculiarities will be seen to be of considerable interest, the more so as few double flowers have hitherto been recorded in this order.

HOME CORRESPONDENCE.

Correspondents will greatly oblige by sending early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

Photographs or drawings of gardens, or of remarkable plants, trees, &c., are also solicited.

MAHERNIA ODORATA, OR GLABRATA?—This is a charming old Cape plant, which I fancy has been long lost to European gardens from its life never exceeding two years, and requiring continual re-propagation by cuttings. It is figured by Andrews in vol. ii. of the *Botanists' Repository*, plate 85, and also in the ninth volume of Morren's *Belgique Horticole*, plate 19. It has yellow bell-shaped flowers, produced in great profusion, which exhale the perfume of the Jonquil, and one plant is said to perfume an entire greenhouse. It does well planted out during the summer. Plants of this introduced—good old plants—are now offered in New York at 30 cents, or two for 2s. *W. E. G.*

BRUGMANSIA CULTURE.—If Mr. Freeman's conservatory is not too small, I advise him to plant his *Brugmansia* out in free soil. This will save him a deal of trouble and his plant will grow more vigorously and flower more profusely than if grown in a tub or pot. The finest flowered *Brugmansias* I have seen have been planted out and a huge specimen I saw last year was planted out in a small border completely filled with roots, and yet it received no manure, only an annual top-dressing of good loam and leaf-mould. The chief points to observe with planted-out *Brugmansias* are to give ample drainage, so that the plant may be deluged with water during active growth, to give it good root-room in a soil of loam and leaf-

mould, to prune it annually after flowering as hard as possible, and to thin out the weakly shoots in spring. If the plant is young and small when planted out a little manure-water now and then will assist in building up a strong specimen, which is the object in view. After that little attention is required. The house should be cool and airy as most conservatories are. A profusely flowered Brugmansia, whether the red sanguinea or the white arborea or suaveolens, is one of the grandest sights that an autumn garden can produce. *W. G.*

PEA, THE STURDY.—This is not only one of the very best quality Peas, but it is equally good in cropping qualities. Last June I made two sowings of it, by the side of my especial favourite, Ne Plus Ultra. The season of course was an extraordinary one for trying the constitution of Peas; still, the one under notice withstood the severe test exceptionally well, yielding us remarkably heavy crops late on in the season, of large and well filled pods containing as many as from nine to eleven good Peas in each. I think it almost needless to say that any variety which grew and produced satisfactory results under such a trying season as that of last year, is well deserving of mention through your columns before the order sheets are completed. *H. Markham, Mereworth Castle.*

THE ROYAL HORTICULTURAL SOCIETY.—I think that in the second paragraph of your leading article last week, you struck a note which will find response in the minds of many of our Fellows, and which many seem to have overlooked. Are we not getting too botanical? Let me put the case as I feel it. Our charter was granted to us for the promotion of horticulture. On referring to the dictionary I find that word to mean, "the art of cultivating or managing gardens; the cultivation of a garden; the rearing and management of flowers, fruit, and vegetables in a garden." The dictionary may be wrong—I may be wrong; but I would suggest that the above is a very good description of what we ought to do. Take the history of a newly introduced plant; its first visit is rightly to Kew, where it is properly examined, dissected, and classified, and its proper place in the botanical world settled; specimens are carefully dried and put away for future reference, and having been scientifically described, it is given a Latin name, after which, unless it possesses some medicinal or utilitarian properties, or is of exceptionally botanical interest, it has practically done with that excellent establishment. Now it comes to us, say the Royal Horticultural Society: we begin striking, grafting, layering, &c., as the case may be, to find out the best means of propagating it; then seeding or hybridising it with some other allied species, to see whether we can improve or raise varieties of it; the results are then brought before one of our two committees (who are doing the real work of the Society), either Fruit or Floral, as the case may be, and adjudicated upon; and it is quite possible that in after years, if some of these results were sent back to Kew, they would have to look twice at them to recognise their old friend. The Society, then, ought to see that these plants are brought properly before the Fellows and the public, and superintend, as it has often most usefully done, the distribution of them. There is plenty of work both for scientific botany at Kew, and practical horticulture for the Royal Horticultural Society. When we begin to get botanical we are trenching on the prerogative of Kew: this I maintain is a mistake—we ought to be purely practical: if we are not practical, we are not carrying out our charter. *W. Marshall.*

— I fully endorse your sensible, truthful and practical remarks relative to the ill-fated Royal Horticultural Society, of which I have been a Fellow for a very long period under the three Presidencies of Lord Aberdeen, Lord Bury, and Sir Trevor Lawrence. Surely, with influential members on its Council, there should be no difficulty in getting the amount of £3000 for the current year. Let the present small band of Fellows double their subscriptions, and in return let them be presented with an additional transferable ticket for one of their family. If our present worthy President organised an entertainment in May, in the shape of a bazaar, afternoon reception, ball, or night *fete* it would bring a certain amount of gist to the mill. *H. Guedalla, Lynnwood, Bath Road, Bournemouth.*

— I believe that we must have now as our President a member of the Royal family, and we must hold one show a year at least in the country, as the Royal Agricultural Society does. That Society would not exist if it were not for the itinerant shows. Well-

wishers of the Royal Horticultural Society must remember that nine out of ten horticulturists never come to London; moreover, according to the *Journal of Horticulture*, the fortnightly meetings next year are all fixed for Tuesday. How is it possible for gardeners to send up parcels, unless sent on the Saturday, to arrive in time for the committee. No parcel sent on Monday morning by post or otherwise is delivered until Tuesday afternoon. It appears to distant country gardeners that those living near London get advantages which should be shared by the country at large. *W. C. K.*

CHRYSANTHEMUM JUDGES.—It would be exceedingly interesting if "Exhibitor" (p. 817, vol. ii., 3rd ser.) would define what he means by a "theorist" in relation to Chrysanthemum show judges. The trotting out these hackneyed and contemptible phrases, "theorist," and "practical," as applied to horticulturists seem to indicate that "Exhibitor" is a disappointed person, who seeks to vent spleen upon fancied sections, because hard-up for argument. Possibly the definition is to be found in the late wish that "only growers who have distinguished themselves" should be appointed: that is proceeding very much on the principle that "he who judges fat oxen should himself be fat"—an absurd condition. But are there no men who are presumably theorists who have not the judging capacities in regard to the properties of Chrysanthemums, which growers only are assumed to have? Where are there six men who have, or at least had, better reputations as Chrysanthemum judges than Messrs. J. Wright, G. Gordon, G. George, J. Douglas, R. Dean and W. Earley, for

FIG. 16.—ERIOSTHEMUM OBOVALIS: DOUBLE FLOWERS. (SEE P. 81.)

instance?—and yet I am not aware that either of these are, or for a long time have been, growers, much less exhibitors of Chrysanthemums? If such broad-minded men as these are to be shut out from making awards, in what respect can confidence be placed on their judgments? Chrysanthemum growers get to be rather egotistic, and somehow seem to hold that only those who grow flowers can be expected to know what a good flower should be: that is an absurd idea. Still farther, a man may be an excellent grower but have the most narrow and non-judicial mind. The wrangling and jangling that visitors to Chrysanthemum shows are too often troubled to hear from exhibitors after the awards have been made, prove that men may be the best of growers and the worst of judges. To grow plants or flowers well is one thing, to be able to judge well is quite another, and far from being the characteristic of all. The best of judges is the man who goes to his work with ample knowledge and a perfectly open mind. The worst judge is the man who is readily open to bias, or enters upon his work with strong prejudices in reference to the subjects of his work. I am at a loss to understand why it is more desirable that the name of the judges at Chrysanthemum shows should be published in the schedules than in the case of other or mixed exhibitions. In myriads of cases such an arrangement is not possible, and even if it be done, in no case can it be shown that the work is better done or the awards more equitably made, than is the case when there is no such publication. If confidence be placed in the executive of a society that it will honourably conduct a show and discharge faithfully its pecuniary obligations, certainly faith may be placed in that body that it will provide good judges. This demand no doubt arises from some disappointed person, who puts his want of success rather to the credit of some unfortunate judge than to his own inability to produce

good exhibits. It is useless to expect that with even angels as judges everybody would be satisfied. No matter who makes the awards the unsuccessful exhibitors are ever discontented: and then they put forth all sorts of suggestions with respect to the judges, as palliatives. Exhibitors should remember that even if judges' names were published in the schedule, yet a score of things may arise between its issue and the show to prevent one, two, or more from attending. In such case what has been gained by publication? The only satisfactory arrangement would be found in having at shows all prizes and no blanks. *Spade.*

THE WEATHER IN SCOTLAND.—An Aberdeenshire correspondent, writing under date Saturday, the 14th inst., says:—During the present week the weather has been of quite a phenomenal character. The temperature on Sunday and Monday was as high as 55° and 56°, which is said to be the highest point it has reached in Aberdeenshire at this period of the year since 1868. Bees were working as if it were summer, and wasps are reported to have been observed near Aberdeen.

FORCING THE SKIMMIA.—At p. 19 it is stated that the *Skimmia japonica* "forces well." As I have never seen or heard of *Skimmias* being forced, I should be glad to know what advantage is gained thereby. It is so unusual to force an evergreen that the statement is singular. *Enquirer.*

ARAUCARIA IMBRICATA.—There are in these gardens two fine specimens of this tree which were planted about thirty-five years ago, but which, although apparently in robust health, are gradually losing their lower branches. I should be glad to be informed if this loss of branches is the natural consequence of age, and whether there is any remedy for it. The trees stand on an eminence close to the coast, fully exposed, and have a stronger and more compact habit than I have noticed in others planted in more sheltered positions. The soil is a light loam resting upon limestone. *Edwd. Cockbill, Clevedon Hall, Somerset.*

THE PRICE OF HONEY.—My experience as to the difficulty of obtaining a fair price for British honey exactly corresponds with that detailed by an "Amateur Beekeeper" in your number of January 14, and agree with your correspondent that Mr. Chitty's felicitations are altogether illusory, not only in regard to the prices offered in London, but in the country. I was induced to extend my stock of bees from hives, and to provide myself with a number of appliances connected with the modern system of bee-keeping, by representations as to the assumed demand and profitable sale of pure honey. Although I did not indulge in all the mechanical aids recommended by professional apiarists which fill a good sized catalogue, I spent a considerable sum in the belief that I should be reimbursed by the sale of the produce of my hives, and my disappointment is very real when I look upon my large unsold stock of sections filled with honey as good as can be produced in this country, for I provided my bees with a succession of the best nectar producing flowers, and I am satisfied that the result has justified that experiment as far as the quality of honey is concerned. I was induced at the end of the last year to send examples of the produce of my apiary to a honey fair held annually in a neighbouring town: eighty-eight sections of comb honey out of 105 remained unsold. I was induced by the representations made in your columns by your bee correspondent, Mr. Chitty, to purchase an extractor, which was said to combine every good quality. I found the instrument troublesome to work and practically useless, and it has remained a dead loss on my hands. *W. Ingram, Belvoir.*

GARDENERS' ORPHAN FUND.—This excellent institution is so exceptionally deserving of generous support, that one would think it almost impossible for any gardener, having the slightest sympathy for the destitute orphans of deceased members of his own profession, to withhold altogether his support from such an institution; at the same time I can quite understand some gardeners having large families, and not receiving very high wages, not being able to become subscribers of 5s. per annum, although many would cheerfully give a smaller amount; this being the case, I have been wondering by what means suitable opportunities can be given to such as would like to give their small

silver or pence, therefore, I will take the liberty of making the following suggestion, which I hope the committee and gardeners generally throughout the country will find worthy of consideration, viz., that the committee shall consider the advisability of having some suitable money-boxes made, each one to be numbered and have the words "Gardeners' Orphan Fund" printed thereon, these boxes to be supplied gratis to all gardeners, managers in nurseries, nurserymen, or secretaries of gardeners' associations and flower shows who may choose to have them to place in suitable positions for the reception of voluntary contributions in the way of pence from the men under their charge. But in order that all contributions shall be purely voluntary, and that under gardeners shall not think that the head gardener or manager wishes to take undue advantage of his position, I think it would be wise to consult them in the matter and see if there is a general desire for a box to be placed in the establishment. If this is done, I would venture to predict that in nine cases out of ten the box would be most welcome, and contributions cheerfully given. In no case should the thing be forced, but, on the other hand, the men should be made to clearly understand that the question of giving is purely optional and in no way compulsory. Something may also be done by placing a box upon the table at the meetings of the various gardeners' societies and flower shows throughout the country; of this, I am quite sure, inasmuch as I have received the ready permission of the members of an important gardeners' association in the Midlands, to place a box upon the table at their fortnightly meetings, and this I have done with fruitful results. My own men under me, too, expressed a desire for a box in which to drop a copper occasionally, and as you may guess, the want has been supplied. Would it be too much to ask honorary local secretaries to undertake the distribution of such boxes in populous districts and collect their contents twice a year? In the case of a popular secretary I think this would be a great advantage. I myself being a local secretary in a large district, shall be only too pleased to do all I can to forward the movement, and I now appeal to my fellow gardeners to come forward and let the committee see that there are willing hands and hearts to help them forward in their charitable work, for I know of no charitable act more genuine than when a person does or gives something to relieve the wants of friendless and fatherless children. I shall be glad to see the opinion of gardeners in higher position than myself, for which, I am sure, you will gladly find space. *J. H., Birmingham.*

THE TWO BEST GARDEN PEAS.—If our garden Peas were reduced to two varieties, and the two mentioned by "Daring" retained, this would have the effect of reducing us here to one variety—*Ne Plus Ultra*—as Veitch's Perfection is not worth growing on our soil. I had seen this variety do so well in several different counties, that I decided, on coming here, to grow it largely. The first season I sowed 4 quarts for a trial, and I question if the produce was as much as the seed sown. I tried it for two more seasons, with the same result. Since then British Queen has been grown instead, and if I were confined to one variety this is the one I should choose. *E. Butts, Irigham Court, Streatham Hill.*

—"Daring" is justified in using his cognomen. Apart from the needlessness of selecting two Peas only out of some 200 or more kinds, there is much courage needed to name the particular two, and it is very probable that no two gardeners would entirely agree. In the first place, so far is Veitch's Perfection from being an early Pea, even if sown early, that many good kinds will beat it for speed a long way. In the second place, even if sown early, the seed being of a soft, wrinkled nature, is very apt to decay when the spring is cold and wet. I should never think of making a selection of garden Peas that did not include William the First for early work as being the best all-round early Pea we have. I do not mind asserting that two or three dishes of first early Peas, if not gathered too quickly, are more delicious eating than are any which follow, when Peas become abundant. But were I going to make a definite selection of a couple of Peas, I should prefer Sharpe's Triumph, a superb wrinkled marrow of medium height, and a great cropper, without in any way being stigmatised as an exhibition variety. Then for the other, commend me to Sutton's Latest of All, also a marrow of medium height, with pods as green as those of *Ne Plus Ultra*, and borne in great profusion for a long season. It is only a question of period of sowing to have these two fairly dwarf Peas cropping from July to October. Add William the

First for first early cropping, and my selected trio is complete. However, in face of the fact that some twelve to fifteen new kinds of Peas have been just added to our lists, we may defer selection of two only to the Greek Kalends. *Spade.*

LAPAGERIA ROSEA IN THE OPEN AIR.—It may perhaps interest some of your readers to hear that we have against the wall of the mansion facing south a plant of *Lapageria rosea* in fine bloom. The foliage is very robust, and the flowers of very deep rose colour, and very beautiful. It is quite in the open air, and has received no protection whatever during the year and a half that it has been in its present position. It was originally in our conservatory, and since its change of quarters it has done much better than when it was indoors. The soil in which it is planted consists of peat, strong loam, and mortar rubbish. It has withstood 18° of frost. *C. Hazel, Gaunt's House, Wimborne.*

BEDDING OUT.—If the exigencies of space had permitted the Editor to insert my letter on this subject in full in the issue of December 17 last Mr. Jeffrey would have seen from the combination of plants that were suggested, the idea I wished to convey was that of a series of groups in an irregular border, and that in each the aim was to let permanent plants form the greater part of each group, the intervening spaces being filled in with summer bedding plants, which spaces could, of course, as well be filled with plants that bloom in the spring and early summer, and which could be removed in time to plant others that will make the garden gay during the three summer months when most wanted. In the case of bulbs it would not be necessary to remove all of them before planting other things. In a border that has a margin of *Crocus* 1 foot wide the space occupied by them could be planted with *Herniaria glabra* before the *Crocuses* begin to grow in the spring, spaces filled with *Scilla sibirica*, and we plant blue *Lobelia* between them just as the foliage begins to decay. If the ground be planted with the autumn *Crocus* the foliage of these will cover the soil in the spring, and as soon as it dies off *Mesembryanthemum cordifolium variegatum* can be planted between, which if pegged down close at the end of August will make a beautiful carpet to show off the *Crocus* which will appear in September. In a straight border here we have clumps of different varieties of border *Narcissus*, 2 feet across, placed at regular intervals: these make a good show when in bloom, but the bulbs are so thick together that it is impossible to plant between them; so as soon as the foliage turns yellow and looks untidy we cut it off, put a little good soil on the top, and plant some of the dwarf *Sedums*, such as *Sedum glaucum*. These are only a few instances, to show how much may be done to make a garden interesting at all seasons of the year. *G. B.*

BEE-PLANTS FOR LARGE BEE FARMS.—Planting for bees has already been considered in the *Gardeners' Chronicle*, and several plants were recommended, but hitherto small patches of ground, or at the most plots of 2 or 3 acres only, were thought of. I have lately turned my attention to the matter on a much larger scale. There is no hiding the fact that land is going out of cultivation—land which ought to and might be made remunerative. Large bee farms might be established in many places. No person in England better understands how to turn bee farms to account than Mr. Simmins, of Rottingdean. In his book called *A Modern Bee Farm*, he clearly points out how a few acres of land may turn out profitably for the farmer and the beekeeper. In planting note these words, which are his:—"Bees need at least six weeks to regain lost numbers after winter is past; they require just as much time to settle down quietly before the cold season comes on." As I can fully endorse this, it is evident that very late forage for bees is undesirable. Mr. Simmins mentions the following as excellent:—*Melilot* Clover, *with Borage*; *Trifolium*, *Sainfoin*, and *white Clover with Crocuses*. The words in italics mean that the two crops are to be in the same piece of ground at the same time. For instance, a large piece of ground could be filled with *Crocus* corms, about 6 inches apart. These and *white Clover* could be planted at the same time. In the spring the *Crocuses* will come first, and will not be in any way injured by the *Clover*. After the *Crocuses* are gone off the *Clover* would come into bloom, though of course not immediately. The gap could be filled up with *Sainfoin* or *Trifolium* in another field. In July the

Clover could be cut, and the grass of the *Crocuses* would come off with the *Clover*. Then a second crop of *Clover* would follow, and thus three crops could be got off one piece of ground in a year. There would be no difficulty in disposing of the *Clover*. So with *Melilot* *Clover* and *Borage*. The ground can be prepared, and these planted at the same time, and in this case there would be two crops off one piece of ground. In the cases mentioned very little time is required to clear the ground. This is important, as time could not be spared by the beekeeper for much clearing of ground. *Walter Chitty, Pusey.*

EVIDENCE OF SPRING.—A market gardener who grows fruit somewhat largely for market stated the other day that the Pear buds were plumping up fast, and becoming very brittle, owing to the mildness of the season, and in the course of pruning there was great danger of breaking the buds off. The moral he drew was that it is advisable to prune without delay. As the weather is now frosty and drying, it is a good time to get through the necessary work of pruning. *R. D.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 10.—Present: Mr. F. P. Pascoe, Vice-President, in the chair; Messrs. Boulger, Lynch, Smith, O'Brien, Michael, MacLachan, Ridley, Murray, Morris, Smeed, Wilson; Professors Church, Scott, Ward; Drs. Low, Masters; and Hon. Secretary, Rev. Professor G. Henslow.

Hybrid Rhododendrons.—Messrs. Veitch & Sons sent five hybrids between East Indian forms, interesting as showing the effects of colours. The crosses were as follows:—1. Female, *Rhododendron jasminiflorum*, from Malacca (white); male, R. Curtis, from Sumatra (small and scarlet). Hyb., scarlet corolla, a little broader than that of the male parent. Effect: male transferred colour and form; female had no effect. 2. Female, R. *jasminiflorum* (white); male, R. *javanicum* (orange-yellow). Hyb., R. *j. carminatum* (bright red). Effect: male transferred the red colour, but the white female eliminated the yellow. 3. Female, R. Maiden's Blush (very pale pink); male, R. T. Teysmanni, from Sumatra (pale yellow). Hyb., R. *Primrose*. Effect: yellow male transferred colour, unaffected by female. 4. Female, R. Princess Alexandra (large and white); male, R. Curtis. Hyb., R. *Eclatant*, bright red. Effect: male transferred colour, female imparted size. 5. Female, R. Monarch (a hybrid from *javanicum*, but of a more pinky tinge to the orange); male, R. *malayanum* (very small, diameter three-quarters of an inch, but bright red). Hyb., Little Beauty, diameter 1½ inch, bright red. Effect: male transferred red, and eliminated the yellow. The general results observable are—1. The prepotency of the red male flowers and the impotence of white females to affect the offspring. When yellow is present—e.g., in orange—then either white or red can eliminate it (Nos. 2 and 5). The Princess Alexandra (female white of No. 4) arose in a similar way. A cross between the larger-flowered R. *javanicum* (orange) with the smaller R. *jasminiflorum* (white) gave rise to Princess Royal (rose), the yellow disappearing. A further cross of the last with the parent, R. *jasminiflorum*, now eliminated the red; the offspring, however, retained the form and large size of the corolla of Princess Royal and R. *javanicum*. Mr. O'Brien observed that a similar elimination of yellow had occurred in *Begonias*, for B. *Sutherlandi* (orange) crossed by B. *parvifolia Dregei* (white) had given rise to a red-flowered offspring. Abortions afforded another instance.

Rhododendron Carringtoniae.—Baron von Mueller sent a description of this new species, which occurs on almost inaccessible declivities of Mount Obree, at elevations of 6000–7000 feet. The corolla is white. (From *Vict. Naturalist*, November, 1887.)

The Silver Fir Feilium.—Mr. Plowright sent the following communication with specimens:—"The extreme tip of the branches of the Silver Fir are often found bare of leaves and variously swollen and distorted. This condition has been assumed to be the result of injury from their having been bitten off by squirrels or other animals. In the specimens sent herewith, which have been given me by Mr. H. Munro, of Cleveland, Lyme Regis, the mischief is

caused, not by animals, but by a fungus, the so-called Peridermium columnare. Robert Hartig worked out the life history of this fungus in 1880. He found that the *Æcidium columnare*, A.P.S., is a heterociccal fungus, the teleutospores of which occur upon *Vaccinium Vitis-Idæa*, and are known to mycologists under the name of *Calyptospora Goeppertiana* (J. Kühn). The *Calyptospora* is not a British species, so that it is difficult to account for the presence of the acidospores. (R. Hartig, *Forst und Jagdzeitung*, 1880; *Lehrbuch der Baumkrankheiten*, p. 56—61, t. 2.) Professor J. Kühn has, however, recently repeated Hartig's cultures, with this result:—He finds that there are two *Æcidia* on the Silver Fir, the true *Æ. columnare* of Albertini and Schweitz, which has for its teleutospores *Calyptospora Goeppertiana* and another *Æcidium* much resembling *Æ. columnare*, but with a different life-history. This *Æcidium* he proposes to call *Æ. pseudo-columnare*, and it is most probable that the fungus which has injured the accompanying shoots of Silver Fir is Kühn's plant."

Potato with Inwaxerated Beetle.—Mr. MacLachlan exhibited a Potato perforated and with a large internal cavity. A predacious beetle, *Pterostichus madidus*, had somehow entered and apparently could not escape. The lining of the cavity, which had seemingly been excavated by some animal, was provided with a strong layer of cork cells.

Aluminium in Plants.—Professor Church called attention to the fact that though large percentages of this metal are well known to exist in Lycopodiaceae, it was not hitherto suspected to be general in flowering plants, a Japanese chemist having discovered it in *Rhus vernix*, &c., in the gum of the lacquer resin. Professor Church examined Cherry tree gum, gums arabic, tragacanth, &c., and found traces to be invariably present. In the *Analyst* for January it is stated that it is also invariably present in the gluten of Wheat, in this case as a phosphate of alumina. It does not occur in association with the starch. From the precautions taken it could not have been due to the millstones. In all cases it is probably accidentally absorbed by the roots, and plays no part in vegetable physiology.

Orthesia insignis, *Coccus* on *Strobilanthes*.—Mr. Morris exhibited specimens of this newly-discovered "bug" on *S. cuspidatus* from the Economic-house at Kew. It has been described and figured in the *Journal of the Quekett Mic. Club*, vol. iii., p. 169. Mr. Michael observed that its habits did not agree with those cocci of which the larva lie dormant beneath the parent, but the young were always very active. The genus was, in fact, on the border of the *Coccidae*, and its nearest ally was *Iceria*. A discussion followed as to the nature of the secretion of wax. It is generally believed to be renewed, the length of the secretion depending upon the age of the insect. Mr. Browne, in the paper alluded to, says it is spreading, and is now found on *Scutellaria*, &c., in the adjoining house at Kew. Mr. Lynch added, that apparently the same species attacked Acanthaceae plants as well.

Clerodendron, n. sp.—Mr. Morris exhibited shoots of a new species received from Sir J. Kirk from Zanzibar. It is remarkable for having the basal parts of the leaves much thickened and curved for the purpose of support. The upper part of the petiole carrying the blade can oscillate, and become detached. It does not appear to be sensitive, but resembles the hooked peduncles of *Uncaria* and stipules of *Dipladenia*.

Monstrous Pears.—Mr. Henslow exhibited three forms of abnormal Pear growths, which appeared to explain the true nature of the fruit. The first was the Bishop's Thumb Pear, which consists of a succulent rod-like structure, presumably of an axial character alone. In the second a branch bore two or more irregular whorls of leaves with hypertrophied and partly coherent petioles. This case, which does not appear to be common, seems to suggest that the upper part of a Pear—corresponding to the whole of an Apple—consists of the hypertrophied bases of the sepals. The figure of an Apple with so-called "intertaped growth" in *Teratology* (p. 327) would therefore receive its interpretation in that the lower part is axial and the upper foliar. The third case represented a more complete fusion, in that the successive whorls were all welded together.

Dr. Masters describes this form as follows:—"The axis dilates to form the lower fruit without any true carpels being produced, but at its summit a whorl of leaves (sepals) is formed. Above this another swelling of the axis takes place, also without the formation of carpels, and this, it may be, is

terminated in its turn by a branch producing leaves."

Judging from the last specimen, Mr. Henslow was more inclined to regard this "succession of pseudo-Pears" as whorls of leaves with hypertrophied petioles rather than as axial. This view was confirmed and accepted by Mr. G. Murray. The fruit of a Pear, therefore, would seem to be axial below—i.e., from its tapering point up to the base of the carpels, but foliar from thence upward to the summit. Apples, therefore, would have no truly axial part at all.

Plants Exhibited.—Mr. R. J. Lynch brought the following from the Botanic Garden, Cambridge:—*Vanda concolor* (*Bot. Mag.*, 62, 3416), *Cymbidium sinense* (*Lodd. Cat.*, 37), *Moricandia* (*Orychophragmus*) *sonchifolia* (*Bot. Mag.*, 6243), *Acacia platyptera* flore pallida, and Miss Hope's Wallflower, a monstrous form, upon which Rev. G. Henslow undertook to report.

English Pomegranate.—He also showed a small fruit, about 1½ inch diameter, grown on the walls of Emanuel College, Cambridge.

LAW NOTES.

DUNSDON v. MOSS.

CLAIM FOR LOSS OF CROP.

This was an action heard in the Queen's Bench Division on Monday last, before Mr. Justice Stephen, without a jury, and was brought by John Dunsdon, of Furzedown Farm, Streatham, Surrey, market gardener, against Arnold Moss, of 39, King William Street, London (trading as Jacob Wrench & Sons), for the sum of £500 damages, alleged to have been sustained by plaintiff for loss of crop of Early Rainham Cabbage grown from seed supplied by defendant in 1886.

Mr. Lockwood, Q.C., and two juniors, appeared for the plaintiff, and Mr. Tindal-Atkinson, Q.C., and Mr. Earle, appeared for the defendant.

The plaintiff stated that he bought a certain quantity of Early Rainham Cabbage seed from defendant's firm in July, 1886, at a cost of £2 5s, sowed the whole of it on one day, viz. July 22, finally transplanting the produce on to 2½ acres of his land during the months of September, October, and November following. He affirmed that the land was properly prepared for such a crop; the result of his experience, he stated, was that instead of having a good crop of marketable Cabbages in June, 1887, he had a crop of "wild things" all running to seed, and what he said, was an admixture of Kales, Savoys, wild Broccoli, and Brussels-Sprouts. His claim was at the rate of £22 per acre for rent, taxes, manure, labour and other expenses, in fact for total loss of crop. When cross-examined by Mr. Atkinson he admitted that he had sold bunched Cabbages off these particular lots of land amounting to perhaps, £8 per acre, and he could not swear it might not have been over £10, but he had not kept any account whatever of this money; also that he had in addition to the plants obtained from Messrs. Wrench's seed, procured some from a neighbour, and planted these in the middle of one of the fields, and included these in his claim against the plaintiff; that early sowing might cause Cabbages to run to seed the following summer, but early Cabbages always fetched more money than late ones.

Four or five market gardeners were called on his behalf as witnesses; each declared the same thing, viz., "that he had never seen such stuff before as were the plants on these 2½ acres;" but eventually, in cross-examination, they admitted that the runners might possibly have come from the Early Rainham Cabbages, and that early sowing combined with the exceptional character of the winter of 1886-1887, and the peculiarly cold spring of 1887 followed as it was by a sudden change to mild and fine weather, might have caused any Cabbages to run to seed, instead of forming heads.

At the conclusion of the plaintiff's case, the learned Judge said that it was useless to continue the case further, as plaintiff had entirely failed to make out his claim, and without calling on the

defence, gave a verdict for the defendant with costs, remarking that had there been a jury in the case to whom he would have had to sum up, he should have used a few strong expressions as to his opinion of the evidence of some at least of the witnesses called by plaintiff.

THE WEATHER.

Accumulated temperature indicates the combined amount and duration of the excess or defect of temperature above or below 32° F. for the period named, and is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

THE PAST WEEK.

The following summary record of the weather for the week ending Jan. 16, is furnished from the Meteorological Office:—

"The weather has been in a gloomy and foggy condition very generally. Over England and the greater part of Scotland the fogs were unusually dense, damp, and persistent. Towards the end of the period, however, the atmosphere became clearer, although a great deal of cloud prevailed.

"The temperature has continued rather above the mean in Scotland and in the North of Ireland, but has been below in nearly all the English districts, as well as in the 'Channel Islands.' Over central, south, and south-west England the deficit was as much as 5°. The highest of the maxima, which were registered on the 10th, ranged from 47° in 'England, S.W.' and 48° in the 'Channel Islands,' to 56° in 'Ireland, N.' and 57° in 'England, E.' The lowest of the minima, which were recorded on irregular dates, varied from 20° in 'England, S.W.' and 22° in the 'Midland Counties,' to 31° in the 'Channel Islands' and 'Scotland, W.,' and 33° in 'Ireland, N.' During the greater part of the period the range of temperature was extremely slight.

"The rainfall has been scarcely appreciable. At nearly all stations measurable amounts of water were deposited in the gauge by the fogs referred to above.

"Bright sunshine has been very deficient, the percentage of the possible amount of duration ranging from 1 to 19 in Scotland, from 3 to 17 in Ireland, and from 1 to 16 in England. At many stations bright sunshine was altogether absent."

MEAN TEMPERATURE OBSERVED AT CHISWICK DURING THE WEEK ENDING JAN. 28. (AVERAGE OF FORTY-FOUR YEARS.)

Obituary.

MR. JOHN DAY.—By the death of Mr. Day Orchidology has lost one of its most ardent, and at the same time, one of its most respected votaries. Among the amateurs who immediately succeeded the older cultivators, the Harrisons of Liverpool, Mr. Barker of Birmingham, Rev. John Clowes, Mr. Bateman, &c., Mr. Day certainly occupied for years the most distinguished position, notwithstanding that he had Mrs. Lawrence of Ealing, Mr. Rucker of Wandsworth, Mr. Dawson of Glasgow, and other once familiar names for his contemporaries, but whom he has long survived, so that he became well nigh the sole connecting link between the older pioneers in Orchid culture and the successful growers of the present day. The veteran Mr. Bateman still survives, but he has long given up Orchid culture. Mr. Day first acquired a love of Orchids from occasional visits to the collection of Messrs. Loddiges at Hackney, from whom he purchased his first batch of plants, which formed the nucleus of his former collection at Tottenham. From that time he followed up his favourite pursuit with all the ardour of an enthusiast, constantly attending sales and acquiring novelties till his collection became one of the richest and most famous in Europe. It was in this collection that many of the most admired Orchids flowered for the first time, notably *Odontoglossum crispum*, *Cattleya Walkeriana* var. *dolosa*, *Laelia elegans* *Wolstenholmie*, named after the deceased gentleman's sister, *Cypripedium Stonei*, and the wonderful variety *C. platyanthemum*, of which Mr. Day acquired the only plant that has ever been imported. This fine collection was dispersed at Stevens' Rooms in the spring of 1880. From an early date Mr. Day accustomed himself to make coloured drawings of the Orchids in his collection, and after its dispersion he continued the practice with unabated energy to within a few weeks of his demise, visiting for that purpose the collections of the leading London nursery firms, and occasionally Kew, Burford Lodge, The Dell, and Downside. These drawings are contained in upwards of fifty "scrap books," and constitute probably the most valuable collection of cultivated Orchid illustrations in existence. They are all faithfully rendered, many of them of exceptional merit, and as the botanical details of the Orchids from his own collection are given, that portion of the drawings has a special value of its own. Mr. Day's love of Orchids led him on several occasions to travel to their native homes; he visited India (more

than once we believe), Jamaica, Brazil, and last year, Ceylon and southern India, during which journey it is feared he contracted the first symptoms of the malady to which he succumbed. Since the dispersion of his first collection he has formed a smaller collection of Orchids, into which none but very choice, kinds, or of exceptional interest, have been admitted. For some time past Mr. Day took the warmest interest in the progress of Messrs. James Veitch & Sons' *Manual of Orchidaceous Plants*; the MS. of the genera already published, and of two or three of those not yet issued, being carefully perused by him, and many valuable hints were given, for which his long experience and extensive knowledge of the subject rendered him thoroughly qualified. *Cypripedium Dayanum*, *Masdevallia Dayana*, *Laelia pumila* *Dayana*, *Coleogyne Dayana*, and many other fine Orchids will perpetuate his name far into the future.

ENQUIRIES.

"He that questioneth much shall learn much."—BACON.

MIGNONETTE.—Could any of our readers afford "A. E." information as to the varieties of Mignonette grown to supply Covent Garden Market, and how it is managed, and how got into bloom by the first week in August? "A. E." states that his object in inquiring is not commercial, but charitable.

NOTICES TO CORRESPONDENTS.

BOOKS: *C. E. Cassell*—yes, Henfrey's *Elementary Course*, 4th edition. (Van Voorst.)

BOX EDGING: *H. H.* This may be cut in the late spring, when there is no longer danger of it being made brown by frost; and again in August, when a slight new growth will be made afterwards that will preserve the sightliness of the Box throughout the winter.

CAMELLIAS: *J. G.* "Them Camellia" leaves have the appearance of having been fumigated heavily with tobacco-paper. The shoots are healthy, and the foliage large and of fair substance. If neither tobacco-smoke nor the injurious fumes from the stove-hole have reached them, please send to us some roots of the plant, a piece of the injured foliage, and some of the soil of the border.

CROSNES: *L.* The Japanese Crosnes figured by us recently are advertised by M. E. Watelier, Rue de Pontoise, Argenteuil, France.

"ECLIPSE" APPARATUS: *C. D. H.* We know nothing about this. Would you kindly send the notes and the illustration.

ERRATUM.—Page 49, January 14.—In the notice of Fellows elected to the Royal Horticultural Society, for John H. Tite read John H. Lile.

EMIGRATION: *Constant Reader.* You may obtain the most trustworthy information from the Emigration Information Office, 31, Broadway, Westminster, London, S.W. The office is in direct communication with the Governments of the various colonies, and was instituted to give such information as you require.

GARDENIAS: *B. A.* There were no symptoms of fungus, or any disease of the tissues, so that we were driven to the conclusions either that something deleterious had been given to the plants, or that there was fault in the management.

INSECTS: *Campe.* The insect which is said to have eaten all the leaves off an Orchid is one of the imported species of cockroaches (*Blattidae*) occasionally found in hothouses. Search for them after dark. *I. O. W.*—*F. W. B.* We failed to find the insect that was said to feed on the parenchyma of the *Chrysanthemum* leaves.

LAPAGERIA IN SLATE TUBS: *J. D.* This plant is most successfully grown, when planted out in a well drained border of rough peat and loam, with a good addition of charcoal broken small, coarse sand, and broken sandstone. It is best to put no manure with the materials, unless the loam be of a very poor character, and then only a little leaf-soil. The border may be of any width over 6 feet, and should it become crowded with roots, assistance

may be afforded by occasional waterings with guano-water during the growing season. If you must grow your plants in the slate tubs, use the compost above-mentioned. Guard the young shoots from slugs by putting glass tubs over them.

LÆLIA: *Norman C. Cookson.* It belongs to the finest type of *Lælia anceps* *Stella*.

MEALY-BUG ON VINES: *Constant Reader.* No, do not burn sulphur in theinery, unless you would destroy the Vines. Read "Fruits under Glass" in our issue for January 14 for a remedy.

MUSCAT VINE ROOTS: *S. K.* The roots sent were entirely destitute of rootlet, and partially decayed, and indicated the worn-out sour state of the soil in which they grew. The soil sent showed by its texture, appearance, and odour, that that is so. Make a new border, and plant new Vines.

NAMES OF FRUITS: *Scarborough.* Apple: Kentish Gouf. Pears: 2, Lewis; 3, Bourré Diel; 4, Bellissime d'Hiver; 5, Winter Bon Chretien.—*Oxford.* 1, Hanwell Souring; 2, not known; 3, Winter Hawthornden.

NAMES OF PLANTS: *J. W.* *Physalis alkekengi.* A hardy plant, seeds of which may be obtained from any seedsmen. The plant is an annual, easily raised from seed sown in the open air in spring.—*C. E. F.* *Tocoma capensis* was given on January 14, under "X. Y. Z.," your letter having been mislaid.—*W. J. A.* *Odontoglossum odoratum.*

PLAN-DRAWING FOR PARKS AND GARDENS: *Constant Reader.* We know of no examinations in this subject. The "much value" in painting flowers would be chiefly as affording you gratification. The money value is but small, too many persons being engaged in the work.

SPRUCE: *W. G.* You must keep a watch on the trees. We expect the mischief has been done by birds (crossbill?), or perhaps by squirrels. We do not think any weevil has caused the damage.

JENSEN'S

Every grain fertilizes because the Guano is perfectly pure. It is most economical, one part of Manure to 100 parts of soil being ample for garden use.

FISH-POTASH

FISH-POTASH contains Ammonia, Phosphates and Potash in large proportions, which are the principal elements of fertilization.

GUANO.

GUANO—2-lb. Tins, 1s.; in Bags, 7 lbs., 2s.; 14 lbs., 4s.; 28 lbs., 6s. 6d.; 56 lbs., 10s. 6d.; 1 cwt., 16s.; 2 cwt., 30s. Special terms for larger quantities. Analysis guaranteed.

J. JENSEN & CO. LIMITED. 109, Fenchurch Street, London, E.C.

STRONG FOREST TREES.

ALDER, 1 1/2 to 2, 2 to 3, 3 to 4, and 4 to 5 feet. ASH, 1 1/2 to 2, 2 to 3, and 3 to 4 feet. BIRCH, 1 1/2 to 2, 2 to 3, 3 to 4, and 4 to 5 feet.

All these are stout, good plants, and properly rooted. The prices quoted will be very reasonable in order to clear.

BEGONIAS (TUBEROUS).—Davis' West of England Collection of New, Rare, and Beautiful varieties, for Exhibition, Conservatory, or Bedding. PRICED LISTS free. Special offers to the Trade by dozen, 100, or 1000.

CHRYSANTHEMUMS.—Descriptive CATALOGUE of 1000 new and old varieties considered worth cultivation, with Cultural Directions, by E. Molyneux, written specially for this Catalogue. Post-free four stamps.

FOREST TREES, &c.—Ash, 1 1/2 to 2 feet, 12s. per 1000; ditto, 2 to 3 feet, 16s. per 1000. Beech, 1 1/2 to 2 feet, 11s. per 1000; ditto, 2 to 3 feet, 18s. per 1000.

PLANTING SEASON UNEQUALLED FOR "QUALITY" "VARIETY" & "EXTENT." PRICED CATALOGUES & ALL PARTICULARS ON APPLICATION. "JAMES DICKSON & SONS" "NEWTON" Nurseries, Chester.

CARSON'S PAINT

Patronised by H.R.H. the Nobility, Gentry, and Clergy, for all kinds of OUTDOOR WORK, CONSERVATORIES, Greenhouses, Frames, &c. 1 Cwt., and Oil Mixture, Free to all Stations.

CARNATION "GLOIRE DE NANCY."

Without doubt the grandest Carnation ever sent out for Cut as well as Conservatory and the Open Border. Flowers from 2 to 3 inches across, pure white, and strong clove-scented.

SIMPLE INSTRUCTIONS by which anybody anywhere may force and obtain a great quantity (lasting until outdoor beds are in full bearing) of most excellent ASPARAGUS at a very trifling expenditure of time or money.

JERSEY FRUIT TREES. Carriage Paid. Cordons a speciality. Write for Illustrated Catalogues to JOSHUA LE CORNU AND SON, High View Nurseries, who will send carriage paid for cash with order, FIFTY JERSEY ROSES for 21s.

ORCHID PEAT, best quality; BROWN FIBROUS PEAT for Stove and Greenhouse use, RHODODENDRON and AZALEA PEAT. Samples and Prices to WALKER AND CO., Farnborough, Hants.

WOOD & SON WOOD GREEN. A Sterling Novelty for 1888. "FERTILIZING MOSS."

Intelligent Plant Growers will find this medium for Plant Culture to be eminently useful. It suits both Soft and Hard-wooded Plants, Ferns, ORCHIDS, and Succulenta.

ECONOMY IN THE GARDEN. WOOD & SON WOOD GREEN. A Sterling Novelty for 1888. "FERTILIZING MOSS." It suits both Soft and Hard-wooded Plants, Ferns, ORCHIDS, and Succulenta.

By Royal Letters Patent.—Carbon Cones.

LETHORION (VAPOUR CONE).

For the distribution of certain principles in a state of vapour, in Greenhouses and Conservatories, whereby their active properties are most closely brought into direct and intimate contact with vegetable productions, for the purpose of DESTROYING PARASITIC LIFE with a certainty hitherto unachieved, and without hurt or prejudice to the most delicate and fragile organization of plant life.

Table with columns for Cone No., quantity, price per cone, and price per case.

Manufactured under the Patent solely by CORRY, SOPER, FOWLER & CO. (LIMITED), LONDON. Sold by all Nursery and Seed Trade throughout the United Kingdom.

Any one of the Four Volumes completed (1881-2, 1882-3, 1883-4, 1884-5), bound in cloth, lettered, with Comprehensive Index, for £1 10s. (or R18), carriage prepaid.

THE *TROPICAL AGRICULTURIST*, As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the *Tropical Agriculturist* stands unrivalled, the work being constantly in the hands of Native as well as European and American Agriculturists. Being a Monthly Periodical the *Tropical Agriculturist* lies on the table and is very often referred to during each month—a fact which Advertisers will know how to appreciate.

Mr. W. T. THIBELTON DYER, F.R.S., C.M.G., Director of Kew Gardens, writing of the *T. A.*, writes to us "an astonishing repository of everything relating to the Economic Botany of the East."

For the Sale of Plants, Seeds, Machinery, Implements, &c., used in Tropical (Tea, Sugar, Fibres, &c.) Agriculture, no better Advertising Medium exists.

NEW POTATO, "COME TO STAY." — OUR PERSONAL FRIENDS in the neighbourhood where the above was raised privately advised us respecting it, and long before being in commerce, consequently we secured a large supply. Its edible qualities quite confirm our friends' description. We believe it will prove the best variety for both garden and field culture ever introduced, and become the favourite **7 lb., 6s.; 14 lb., 9s.** The Best and Most Correct CATALOGUE bearing on Vegetables and Flowers ever sent out, sent Post-free to previous, present, and coming Customers.

"MYTICUTTAH"

Large size.
Price in box 9/6
Post-free 7½d. extra.

PATENTED IN GREAT BRITAIN, FRANCE and GERMANY.

As the S. M. Co.'s "Standard" Tree Pruner is admitted to be the best Pruner for work a distance from the ground, so will the two "MYTICUTTAHS" prove the handiest and most powerful for Pruning and Trimming close to the ground, such as the removal of shoots from roots of trees; also Shrubs, Fruit and Flower Bushes, Vines, and other climbing plants, &c. Their construction enables prickly Shrubs and Bushes to be Pruned without lacerating the hands or wrists, even if gloves are not worn. They will with ease cut the hardest wood growing without injuring the part left by splitting and drawing the sap several inches up and causing decay, as other implements are known to do.

For Illustrated PRICE LISTS of above and other NOVELTIES in PRUNING TOOLS, FRUIT and FLOWER GATHERERS, &c., apply to the

STANDARD MANUFACTURING COMPANY,
ST. ALKMUND'S CHURCHYARD, DERBY;

MESSENGER & CO.'S New CATALOGUE of Greenhouses and Heating Apparatus,

Just issued, will be found the most complete, practical, and reliable guide to all about to build, alter, or heat greenhouses. Illustrations of every description of Glasshouse, from the largest range of Winter Gardens to the simplest forms of Portable Greenhouses, Plant Protectors, and Garden Frames; also of all the best kind of Boilers, Hot-water Pipes, and all appliances for heating. This Catalogue, possessing hundreds of illustrations of all the latest improvements in greenhouse building and heating, is on a scale never before attempted. It should be in the hands of every one interested in gardening, as it contains many practical hints on the subjects of which it treats, the result of many years' experience. Price 2s. post-free.

A large number of the illustrations are taken from greenhouses erected by us in various parts of the country, an inspection of this Catalogue shows, therefore, building the efficiency of which has been well tested by actual use. The advantages possessed by us enable us to carry out work with the utmost promptness, and in the very best style, at prices which defy competition. Surveys made and gentlemen waited on in any part of the country. Plans and Estimates free on application.

MESSENGER & COMPANY, LOUGHBOROUGH.

CONTRACTORS TO HER MAJESTY'S WAR DEPARTMENT.

THE THAMES BANK IRON COMPANY,

HOT-WATER and HOT-AIR APPARATUS Erected Complete, or the Materials supplied.

THOMAS GREEN & SON, LIMITED,

SMITHFIELD IRONWORKS, LEEDS, AND SURREY WORKS, BLACKFRIARS ROAD, LONDON, S.E.,

HORTICULTURAL ENGINEERS to HER MAJESTY THE QUEEN, call Special Attention to their

PATENT WROUGHT-IRON MUNICIPAL OR ANGULAR CHAMBERED AND TUBULAR HOT-WATER BOILERS,

And others with SHELVES, and Hollow or Ordinary Cast-iron GRATE BARS.

SADDLE BOILERS, With WATERWAY SHELVES and WELDED BOILERS, any of which are specially adapted for Heating Greenhouses, Conservatories, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c. They are the neatest, cheapest, most effective, and durable of any extant.

The MUNICIPAL and TUBULAR ones are remarkable for their great heating power, slow combustion, and the length of time the fire will burn without requiring attention.

These Patterns secured the FIRST and HIGHEST PRIZE a SILVER MEDAL, at the Royal Horticultural Society's Exhibition, South Kensington, London, June 1, 1881.

FRONT ELEVATION

LONGITUDINAL SECTION

SECTIONAL PLAN.

The longitudinal section gives a view of the fire-box, water space, flues, &c.

The front elevation shows it set in brickwork, which is necessary for this class of boiler.

The cross section gives a view of the fire-box, water space and V-shaped back.

TESTIMONIALS.

MESSRS. THOS. GREEN AND SON, LTD., NORTH STREET, LEEDS. Re HEATING APPARATUS. Borough Engineer's Office, Municipal Buildings, Leeds, January 9, 1886. GENTLEMEN,—I have great pleasure in bearing testimony to the efficiency and satisfactory working of the Hot-water Heating Apparatus you erected in these public buildings. The buildings are four storeys high, and we have a total length of about 28,000 feet of piping in them, varying in size from 1½ in. to 6 in. diameter, with their connections, &c. The several offices and rooms can all be in operation at one time or separately, and the heat regulated by means of the valves to the temperature required, even in the coldest weather. Two of your Patent Municipal Pattern Boilers, No. 4, work the whole of this piping easily, although we have three of them fixed. They are very powerful and economical in the consumption of fuel, and I am pleased to be able to report of them and the apparatus so favourably. I am, Gentlemen, yours truly, THOS. HEWSON, Borough Engineer.

GENTLEMEN,—The large Municipal Boiler which you sent me last year is doing its work satisfactorily; it is heating 5,000 feet of 4-inch pipe in one of my vineries, and I am quite sure that it has power to work a much greater length, while in cost of fuel it compares favourably with my other Boilers. I have now five of your Boilers in use, and I cannot speak too well of their heating powers, and their comparatively small consumption of fuel. Yours faithfully, (Signed) G. W. BASHFORD.

AND HUNDREDS OF OTHER REFERENCES CAN BE GIVEN IF REQUIRED.

100 CONIFERS, in 50 distinct varieties, for 50s.
100 ORNAMENTAL TREES, in 50 distinct varieties, including many variegated, golden and purple Acers, &c., for 50s.
100 DECIDUOUS SHRUBS, in 50 distinct varieties, for 40s.
100 EVERGREEN SHRUBS, in 50 distinct varieties, for 50s.
100 ROSES, in 50 finest varieties of H.P. and Teas on the Seedling Brier from the open field, for 35s.
 We may state that we have grown Teas on the Seedling Brier in the open field for many years back, proving that they are about as hardy as the H.P.'s, as we have frequently had the latter cut back to the snow line; it is only when the thermometer registers below zero that they require protection.
100 HERBACEOUS PLANTS, in 50 fine varieties, for 20s.
100 PRIMULAS, in 50 distinct varieties, for 50s.

(many of which, like the flowers they illustrate, are original),
consisting exclusively of

FLOWER SEEDS.

I have much pleasure in announcing that my New CATALOGUE of Flower Seeds is now ready, and has been Posted to all Customers, who will doubtless welcome it as a valuable Catalogue for reference, and to whom, I am sure, it will prove especially instructive and attractive. Considering that its pages are devoted to Flower Seeds only, it is perhaps not too much to claim, that it is the LARGEST CATALOGUE of these ever published, and includes in its varied columns very many species and varieties, which can be procured from Tottenham only; and while desirous to introduce a large amount of stuff not generally known, I have—as is my wont—had due and proper regard to the fact, that as a rule buyers do not care for specialties unless they are distinct and effective. All the novelties and varieties appearing in this Catalogue claim such a distinction.

Copies may be had Gratis and Post-free upon application.

Kindly mention this Paper when writing for Catalogue.

THOMAS S. WARE,

Hale Farm Nurseries,
TOTTENHAM, LONDON.

"THE DANIELS"
Is the coming **POTATO.**

A cross between the White Elephant and Magnum Bonum, having the unexcelled qualities of both. Ready to lift same time as White Elephant. An immense cropper, and of splendid table quality. All Potato growers should try it.

Price per peck, 3s. 6d.; per bushel, 12s. 6d.; per sack, 30s.

From Mr. J. ERR, Broom Park, Clebury Mortimer, Oct. 29:—"The seed Potatoes, **The Daniels**, I bought of you last spring have turned out remarkably well in quantity as well as quality; I had 286 lb. from 7 lb.; not one diseased."

From Mr. E. PITT, Ventnor, I.W.:—"From 2 lb. of your new Potato, **The Daniels**, I have raised 213 lb., of splendid quality."

A CHANGE OF SEED ALWAYS PAYS.

Before ordering your supply send for **Daniels' Illustrated Potato Catalogue**, containing valuable hints on the Potato, with descriptions of nearly 200 kinds, and the latest Novelties. Gratis and Post-free to all applicants.

DANIELS' GUCUMBERS

Are the Best in the World.

DANIELS' DUKE OF NORFOLK.

A magnificent New Variety, immensely prolific. Handsome dark green fruits, 18 to 24 inches long. Price 2s. 6d. and 5s. per packet.

DANIELS' MASTERPIECE.

A splendid New Variety, exceedingly handsome. First-class for Exhibition, and unexcelled for table. Price 2s. 6d. and 5s. per packet.

DANIELS BROS., The Royal Seedsmen, NORWICH.

VEITCH'S NEW ASTER, DIADEM.

The most beautiful and strikingly attractive variety in cultivation.

This lovely and most desirable new type of Aster is of pyramidal compact habit, much branched, and grows about 10 inches high. For grace and beauty the flowers are quite unique, and a distinct and pleasing variation from all other sorts; they are very double, and of rather small size; the two or three outer rows of petals, being pure white, form a distinctly defined band or margin, in charming contrast to the inner petals, which are bright rosy crimson. This pretty variety is particularly valuable for cutting for bouquets, &c., and will also prove highly decorative for pots, borders, or beds. *Per packet, 1s. 6d.*

For full description of the above, and other Choice Novelties and Specialties see SEED CATALOGUE for 1888, forwarded Post Free on application.

JAMES VEITCH & SONS,
ROYAL EXOTIC NURSERY, CHELSEA, S.W.

ALGIERS.

IN the warmer lands bordering the Mediterranean, and especially in Northern Algeria, the changes of the seasons with regard to vegetation are different from those of more northern regions. Here it is in summer that vegetable life disappears, and the earth rests. The cause is the continual drought characterising this season. From the end of May or the middle of June not a drop of rain falls; a fierce hot southern wind—the fearful sirocco—assists the sun; men and animals breathe with difficulty, and all vegetation vanishes; the harvest is already done, and the Grapes are almost ripe; one has to be content when the leaves are not attacked by insects, so that they fall off and expose the fruits to the influence of the fiery wind. The country has everywhere the appearance of a desert, as is the case in other lands in winter; the rivers are dried up, and the burnt soil nowhere shows any vegetation. In some sheltered spots the species of Citrus keep their leaves, but the hope of their bearing fruit is founded only on continual artificial irrigation; the indispensable water is, however, not to be found everywhere.

To this period of drought—dangerous also to men, and, above all, to Europeans not yet acclimatised to it—a delightful season follows, best compared with the spring in Europe. A well-known scholar, Mr. Durando, of Algiers, who has studied the Algerian flora for upwards of thirty years, says:—"After a three or four months' drought, by which the herbaceous vegetation is completely burnt, rain appears in the first part of October, also often in the first part of September, refreshing the earth. . . . The soil is quickly covered with plants and flowers; it is our spring, and one is always glad to see this sudden change in Nature. Now the bulbous plants appear everywhere in the field; but when they appear in the footpaths or roads they are crushed by

wheels and passengers, and soon disappear. These plants are:—*Merendera filifolia*, Camb.; *Colchicum autumnale*, L.; *C. Bertoloni*, Kunth; *Scilla anthericoides*, Desf.; *S. autumnalis*, L.; *S. fallax*, Steinh.; *S. parviflora*, Desf.; *S. ligulata*, Poir.; *Leucojum autumnale*, L.; *Amaryllis lutea*, L.; *Narcissus cupanians*, Guss; *N. serotinus*, L.; *Spiranthes autumnalis*, Rich.; *Arum arisarum*, L.; *Biarum Bovei*, Blume. Besides these, *Scilla maritima*, L.; *S. undulata*, L.; *Pancretium maritimum*, L.; and *P. collinum*, Coss and Dr., are already flowering in July, and continue so till October. Also may be mentioned *Cyclamen africanum*, Boiss. and Reut.; and *Ranunculus bullatus*, L., two plants the flowers of which smell like Violets; these and *Leontodon tuberosum*, L., with *Thrinax tuberosa*, DC., are very common. The yellow colour spread over the meadows about this time is caused by the flowers of the latter, as in the case with the species of *Ranunculus* in Europe. The children gather the roots, which are called here 'cat's-paws.' (*Association Française pour l'Avancement des Sciences, Congrès de Paris, 1878.*)

At the same time the following plants flower and ripen their fruits:—*Plumbago europæa*, L., with its indigo-blue flowers; *Calamintha heterotricha*, Boiss. and Reut., with a smell like Mint and balm, *Panicum colonum*, Lange and Willk., and *P. Crus-Galli*, L., cover the canals of the artificial irrigations—so they abuse the hospitality granted them; *Cheopodium ambrosioides*, L., from Mexico; this plant, with its aromatic smell, is now naturalised everywhere.

When the first cold is felt—and cold is here about 50°—with rainy weather, the soil is covered everywhere with the large silvery flower-heads of *Bellis atlantica*, Boiss. and Reut.; while *Iris stylosa*, Desf., is now seen expanding its beautiful blue flowers in ravines and other waste places; it flowers continually during the whole winter. Now the dark foliage of the Orange trees shows here and there golden spots intermixed. The Japan Loquat (*Eriobotrya japonica*) opens also its white and strong aromatic smelling flowers.

The upper parts of the Atlas Mountains are now snow-covered. Last year (1887) the first snow appeared during the storm of October 25–27, but disappeared in a few days. In the winter of 1886–1887 the snow covering was not seen before December 1, and lasted continually till the end of March. In a trip in the mountains on April 11 I found large heaps of snow under the Cedar trees at an elevation of 1400–1600 metres; it is, however, not rare to see all vanishing in a single day under the influence of the sirocco. At the foot of the mountains snow is very seldom seen, and even when it falls the flakes are melted as soon as they reach the earth. For the first time since my residence here I saw the country covered with snow for some minutes on February 11 last; it was between 9 and 10 o'clock in the morning; I also saw for the first time ice in the ditches on January 4. It is in general rare to see the temperature go down below the freezing-point; the lowest temperature observed was 25° on January 4 at 7 A.M. When the temperature falls as low as 41° the people believe themselves lost, and are benumbed with cold. In general the temperature varies between 50° and 70°, only when the sirocco blows it rises above 70°. This is the case in winter; in the summer months the heat reaches often above 110° in the shade; the mean for this season is almost 86° at mid-day.

From this it is easy to see that all greenhouse plants will vegetate here in the open air; besides almost all the species of *Citrus*, many of *Laurus*. Of these *Laurus gratissima*, L., *cinnamomum*, and in the first place *L. camphora*. Large specimens of the latter are seen here; it merits to be cultivated at large. (See an article on this subject by myself in the *Moniteur de l'Algérie*, March 4, 1887.) The species of the genus *Psidium*, *Anona*, *Eucalyptus*, and

Acacia, *Eriobotrya japonica*, the already quoted Japan Loquat, and besides a multitude of plants cultivated in the gardens here. I advise those of my readers intending to make a journey to Algeria to visit in the first place the gardens of Marengo, of Algiers, the gardens Bizot of Blidah, of Colea, and the nursery of Miliiana. In one of the gardens of Blidah there is a specimen of the genus *Bombax*.

Last year many of these plants were damaged by the extraordinary cold mentioned above, at Mr. Fontaine's nurseries the following plants:—*Begonia semperflorens*, *Psidium pyrifera*, and *Anona Cherimolia*. A certain species of *Psidium*, with small fruits, of which I do not know the name (it is called here *Goyavier du Japon*), has withstood the cold without injury. In my garden the buds and flowers of a *Justicia*, and also the young branches of *Laurus cinnamomum* were totally lost.

In the month of December flowers are rare; however, there are enough to make bouquets of them. The meadows are covered with luxuriant green. *Bellis annua*, L., forms a carpet which could be taken for snow at a distance.

In January the first Orchids appear in the fields, and in the garden the fruits of the species of *Citrus* are almost ripe; a variety of them has already appeared on our tables in December. The Violets are now seen everywhere on the roadsides, and the Roses are developing. As the season advances the number of flowering plants increases. I have in my herbarium thirty species of wild plants collected in February and fifty in March; the number collected in April and May is too large to estimate.

But the weather in March is not mild even here: I have found it to be the coldest month of the year (with the exception of 1887). On the whole, the weather of this month does not differ much from what we are accustomed to in Europe—wind, cold rain, and often heavy snow fall on the mountains. This bad weather, however, does not last long; when the sun breaks through the clouds spring sets in suddenly. Now an innumerable multitude of plants is to be seen; they are crowded together as if they feared not to get a place at this festival of Nature. It would lead me too far to describe the vegetation during the months of April, May, and June, as such a description would comprise the whole Algerian flora. Notwithstanding this I hope to try it soon, if not of the whole province yet at least of the environs of Blidah. *H. Gay, Preceptor of the Blidah College, Member of the Algerian Meteorological Society and the French Botanical Society.*

PLANT NOTES.

PYRAMIDAL POPLARS.

In my note upon these recently the Editor interpolates "Try Bolle's Poplar." This tree I know well, and consider it one of the most valuable additions to hardy trees of late years. But I think that what I meant to say was not made quite clear. What I meant is this. If the Metz Poplar is in habit of growth between the Lombardy or Bolle's, and the spreading pyramidal-headed Black Italian or Canadian, then it will be an important addition to ornamental trees, for we want a deciduous tree with an outline intermediate between the distinct forms which these trees assume. Too much cannot be written in praise of *P. alba* var. *Bolleana*. It is not much known yet, but it will undoubtedly become as popular as the Lombardy, and will, I imagine, thrive where the Lombardy will not. Being a variety of the Abele, it will probably prove as indifferent to soil or situation as that useful tree is. I am planting it wherever I have an opportunity. *W. Goldring, Kew.*

POPLAR PARASOL DE ST. JULIEN.

In answer to *W. Goldring*, who inquires as to the history of this Poplar in the *Garden*, January 7, p. 2, I should say that its history resembles that of many other varieties in demand by the planter. I will give its history in a few words. In the spring of 1865 one of the foremen of the establishment of Baltet Frères observed a slender, many-branched, reflexed Poplar growing on the bank of a canal at St. Julien, near Troyes. He then procured branches presenting in the most marked degree the character that it was desired to reproduce, and crown-grafted

them. After having proved and studied the new form during two years, MM. Baltet Frères sent it out under the name of Poplar Parasol de St. Julien. It immediately became widely spread owing to its highly ornamental qualities. It is far more beautiful than the old weeping Poplar, and it is also hardy. It is probable (but one cannot affirm positively anything in such a case) that the Poplar Parasol de St. Julien is only a form of *Populus tremula* (the Aspen), a form comparatively recent, and of a more showy aspect than that possessed by the old variety. I may add that it does best when grafted on *Populus alba* (the white Poplar of Holland), and that it does not succeed on the Swiss [?] Poplar. *Ferd. Cayeux, in "The Garden."*

NEW OR NOTEWORTHY PLANTS.

ONCIDIUM CHRYSOPS, n. sp.*

MR. HUGH LOW kindly informs me that this *Oncidium* struck him by its difference from its companions. It has short reddish leaves. The reddish racemose peduncle offers flowers which are distinct from those of the three neighbouring species—*bicallosum*, *Cavendishianum*, and *pachyphyllum*. The cuneate-oblong sepals and the much broader somewhat wavy blunt petals are of a very light brown colour. The basilar lacinia of the bright yellow lip are as small as in *Oncidium bicallosum*, the isthmus is very short, and the large anterior blade is reniform emarginate. The calli are triseriate. There are two large pistillar calli at the base, three filiform acute very small calli in the middle, and three larger terete acute calli in front. The column has falcate deflexed wings, with a tooth in front before they bend down on the superior margin. *H. G. Rehb. f.*

DENDROBIUM BRYMERIANUM (Rehb. f.) HISTRIONICUM, n. sub-sp.

The original type excelled in a glorious fringed beard, comparable to that of the genuine *Dendrobium Hookerianum*; I received later on numerous specimens with shorter fringes, some with none at all. The beardless plant may be easily recognised by its scarious bracts, making one think of *Dendrobium clavatum*, Roxb., and by the rhombic lip.

It was in August, 1886, that I learned that a most excellent observer, General E. Berkeley, had studied the plant; he knew it well from Bhamo, and had found it at an immense distance from that station. Mr. Rimann, then Mr. F. Sander's traveller, informed me of his having found another spot, on the (geographically) right side of the Irawaddy. General E. Berkeley's first specimens were very tall, the stem of course swollen in the middle. The same plant appeared later at Messrs. Hugh Low & Co.'s, who had long before introduced the grand type. Last year it flowered with Mr. F. Sander, and I had the same in 1879 from Mr. F. Kramer from the Rucker-Jensen garden at Klein Flottbeck. I tried to get as much information as I could. Mr. W. E. Brymer, M.P., Ilslington House, Dorchester, was the first who told me of the fact that the fine type is always vernal (spring flowering), while the *histrionicum* (which has sometimes a beard, sometimes none, like a comedian) is autumnal.

General E. Berkeley was so very kind as to send me three strong plants of the present variety from his fresh locality. I was exceedingly pleased to see last year the very same with very neatly bearded lips, which previously had been fully deprived of that ornament. Thus my old belief is confirmed beyond all doubt. The same gentleman called my attention to the quite

* *Oncidium chrysoptis*.—Aff. *Oncidium bicallosum*, Lindl. Sepalis tepalisque cuneato-oblongis obtuse acutis; tepalis latioribus magis obtusis; labelli lacinia lateraibus parvulis ligulatis obtusis; isthmo brevi; lacinia antica maxima reniformi emarginata callis triseriatis posticis geminis divergentibus pistilliformibus scilicet teretibus retuso-capitatis maximis, medianis minimis filiformibus acutis; anticis medio-cris teretibus acutis; columnæ alia falcatis deflexis; angulo supero supra nexuram exeunte. *H. G. Rehb. f.*

regular process of self-fertilisation in the histrionicum variety. It is regular in our plant. Then the General tells me that the Bhamo plant has always the bulbs longer and more slender, whether the plant be large or small. *Lubenter cedo majori*—the General is much better informed than I can be, yet I have obtained very slender specimens from the histrionicum from this high authority.

Just as in the case in the type, it frequently shows some abnormalities in the column. As it is, I cannot find satisfactory reasons for separating it as more than a sub-species. It is, however, exceed-

keels. The disc is covered with seriate gyrose callosities, which might be compared for their wrinkles to those of *Cœlogyne Massangeana*. Of the colour I can say nothing. I think of all my herbarium specimens, one from Moyabamba may decidedly, and that the Lindenian 1263 may probably, belong to this species. If the lip is much pressed and rolled it is exceedingly difficult to find the characters, which are so very easily seen in the fresh plants. *H. G. Rehb., f.*

KOROLKOWIA DISCOLOR, Regel.

We have this new and rare species in flower again

in breadth, with a tinge of red up the midrib on the underside. These leaves run right up the stem into the flower-head, losing themselves in numerous bracts. The flowers are arranged in a terminal head, and number from nine to twelve, and stand individually erect and forward, quite different from the campanulate form of inflorescence in the *Fritillary*. The flowers are from $1\frac{1}{2}$ to 2 inches across, of a light yellow, with a slight suspicion of green in it; segments oblong-lanceolate, slightly reflexed, and at the throat of the flower runs a blood-red ring; anthers prominent, of an ashy-purple colour. The flower

FIG. 17.—*LÆLIA ANCEPS* VAR. *GRANDIFLORA*. (SEE P. 107.)

ingly astonishing that the one variety flowers in spring, the other in autumn. *H. G. Rehb., f.*

WARREA BIDENTATA, Lindl.

I have at hand a fresh (frozen) inflorescence, kindly sent me from Mr. Sander's Transatlantic establishment (59, Storm Avenue, Jersey City, New Jersey, U.S.A.), by Mr. S. Förstermann, the excellent and most successful traveller. Now I see the flowers in a fresh state I feel inclined to think that the plant is quite distinct from *Warrea tricolor*, Lindl. The lip is longer and narrower, not so transverse as in that plant. The keel at the base of the lip is very sharp, and has scarcely any indications of lateral

at Hale Farm Nurseries, Tottenham, and it is doubtless one of the best of Dr. Regel's introductions of late years. It may never become a commercial plant, for the flower lacks that decided colour which such a plant requires, but it would always form an object of interest in a private or botanical collection. A notable distinction between this plant and the *Fritillary*, to which it is so nearly allied, is its being amenable to forcing. By potting in autumn, and then placing it in a warm house, it will flower in about three weeks. In habit the plant is dwarf and compact, about 10 inches in height, with erect, sessile, subamplexicaul, broadly lanceolate, glaucous leaves, fleshy, about 3 inches in length, and 1 inch

gives the idea of a gigantic *Ixia*. A peculiarity of the plant is, that only three flowers of the ten have the pistil developed—in seven of the flowers it is totally absent; the flowers, with this exception, are perfectly normal. There are others coming on, so that I shall be able to observe if this irregularity be constant. *F. E.*

ROYAL SEEDSMEN. We learn that Her Majesty's Commissioner of Works has entrusted Messrs. Oakthott & Millard, Seedsmen to the Queen, Reading, with the order for supplying Grass seeds for the Royal parks.

FERTILISING MOSS.

I AM pleased that one of such well recognised ability as Mr. Roberts finds this subject sufficiently interesting to give the readers of the *Gardeners' Chronicle* the benefit of his experiences and successes with that medium (vol. ii., s. 3, p. 810). I am also glad at the chance it gives of pointing out something of a novel character for intelligent horticulturists in the new year. True, as Mr. Roberts remarks, the system of culture is not quite new; it would be difficult to say when it originated, and yet very few growers have ever turned their attention to it to such purpose as has your able correspondent.

In the summary of the year's events in the various horticultural papers it is unanimously agreed that we have had no striking novelties introduced. Whether this, to many, new mode of propagation and culture will be taken up as a novelty it is too early to say. Plant growers are rather conservative in their treatment of ordinary subjects, and like your other correspondent, Mr. Bell, they are content to know that "fibrous loam" still retains its virtues, and that leaf-mould and peat are always to be relied on for given results. Perhaps, had we a more vigorous and practical united horticultural society at the head of affairs cultural, and not so much taken up with clique and fashion, we might hope—but there, I think it may be as well to let by-gones alone, and to live in hopes of a bright era under the auspices of such a national horticultural society as seems to be looming in the near future.

I am thoroughly convinced that there are many subjects of ordinary culture, both in soft and hard-wooded plants, that rejoice in a much freer and more porous rooting medium than is usually given. Some six years ago I treated the whole of my bedding, and more than half my stage plants with fertilising moss, and as I disposed of or planted out upwards of 30,000 of the former, and sold off all the spare stock of the latter, being afterwards applied to for more in the same condition, I was well satisfied with the results.

My satisfaction arose more, however, from the happy thriving condition of my plants, and one of my "pleasant memories"—and I trust we shall have many such in the New Year—is the mental picture of a large Wardian case filled with perfect little specimens in full bloom and vigour. This group included Fuchsias, Begonias, Pelargoniums, Gloxinias, Coleus, Ferns, and grasses; and as it was sent to embellish a counter in one of the most fashionable "ladies' emporiums" in London, and was there duly admired and wondered at, I had my reward. Not one of these plants had ever felt the benefit of loam or its concomitants. They were reared and bloomed in fertilised moss—most of them even without the aid of pots, the moss being simply bound round the balls, as it seemed desirable owing to the rapid and vigorous ramification of the roots.

Succulent plants, I find, are highly delighted in this medium, and I have no trouble or loss in propagating them in it, the moss being so much more absorbent under control, as regarded its damping properties, than other potting mediums. I am just now turning out a pot of the common spined Cactus that has had no water for over six weeks, and yet moisture is sufficiently present in the ball of moss to serve it for a considerable time. I find that after the moss has lost its fertilizing properties—it does so after being acted on by a vigorous set of roots for six or seven months—it is easier and better to place fresh moss over the surface of the old than to disturb the roots—especially in such examples as the Agave and Cactus. I also find that the plants get great benefit if after the moss has become partly exhausted liquid manure, chemically prepared, be afforded them. From previous experience I am aware that these facts and statements will be dubiously received by some of your readers, and I often wish that circumstances would permit me to set before them at some of our exhibitions a few examples of fertilising moss culture. As I cannot do that I trust the Editor will kindly comment

on the simple example I am sending him for inspection.

Its history is this:—A young, tender growing shoot, 3 inches long, broken off accidentally by a neighbouring gardener, and given by him to one of my little boys, was placed by him into a handful of the fertilising moss, pressed down into a pot. It has been simply afforded water by dipping the whole pot and its contents under water and letting the surplus drain off about once a month. This shoot was brought home in the spring of 1886.

I am quite aware that my system is different from that advocated by Mr. Roberts, but I trust that, as your correspondent Mr. Bell asked "that some one acquainted with the details of moss-culture" would ventilate the matter, you will find my few lines worth printing. The "Dumesnil" moss does not appear to me to suit this system of culture, as it is stated that it should be protected from the roots, or rather *vice versa*. What I use is the same as mentioned by Mr. Roberts, and I know of nothing so good for preserving roots while at rest, and bulbs and corms during the winter time, as it does not entirely dry them off, but on the contrary keeps them fresh and plump. Tuberos Begonias winter splendidly in the moss, and start again freely when required. Soft-wooded cuttings callus very quickly when the moss is kept moist and warm, and such roots may be removed at any time without injury. *E. Abel*.

[The Cactus is in excellent condition, and providing the plant be kept cool it will rest perfectly during the winter. The growth made from so small a piece of *Cereus splendidissima* was as good as could be done in the soil ordinarily employed. Many of our readers will have used moss, and moss commingled with rough peat for covering the shaded walls of stoves and greenhouses with *Selaginellas*, Ferns, and variegated-leaved Begonias, the materials being kept in place by wire netting. This is also in a sense fertilised moss. *Ed.*]

ORCHID NOTES AND GLEANINGS.

SEEDLINGS OF CYPRIPEDIUM.

THESE, so far as our present knowledge goes, are the easiest of Orchids to raise from seed, and are not long in reaching the flowering state. The lovely *C. niveum* is the parent of numerous seedlings, some of which have flowered, and others will do so shortly. A distinct and very handsome hybrid has just opened its flowers in the nursery of Messrs. Veitch & Sons, Chelsea. The seeds were saved from a plant of *C. Lawrenceanum*, whose flowers had been fertilised with the pollen of *C. niveum*. The foliage nearly resembles that of *C. Lawrenceanum*, and the flowers, though much larger than those of *C. niveum*, are more like it than the seed-bearer. The sepals are mottled, spotted, and striped purplish on a creamy-white ground, and the bases of all the sepals are slightly tinged with green.

Another hybrid is *C. Leeanum superbum*; it is one of the prettiest hybrid *Cypripediums* yet raised. The dorsal sepals are almost pure white in colour, with just a slight flush of pink, and measure 2½ inches across. The form *C. Leeanum* is now very plentiful, and as it can be obtained at a cheap price it should be found in every collection. The new *Cypripedium Sanderianum* is also in flower in Messrs. Veitch's; the flowers are much better developed than any I have yet seen. It is a distinct and beautifully marked species; the dorsal sepal is marked in the manner of *C. lavigatum*, and the slender tail-like attenuations of the laterals are much more beautifully marked than those of *C. caudatum*, and are quite 14 inches in length. The upper portion of the tail is densely covered for 1½ inch of its length with fine purple hairs, and has reddish-purple spots; the lip is of a brown colour. The flowers on established plants are expected to be much larger. The plant has larger leaves than those of *C. caudatum*, but is much like that variety in other respects. *J. D.*

GEOBYA AMHERSTIÆ.

A specimen of this curious and interesting little Orchid, which is well figured by Lindley in the *Botanical Register*, t. 1740, is now flowering in the Kew collection. It has the habit and general appearance of a *Laelia*, except that the racemes are drooping. These bear a number of good-sized flowers, very singular in appearance, somewhat honey-coloured, the broad petals being densely spotted with purple-brown spots arranged in transverse bars. The curved column is also barred in front like the petals. The lip is of singular shape, the side lobes being large and membranous, and the front one small and very fleshy. It is a native of Brazil. Lindley remarks that it was sent to him by the Countess of Amherst, in whose collection at Montreal it flowered during the month of September. It had been sent home by Mr. Hayne, a Commissioner in Brazil, from the interior of that country in 1829. The only other species of the genus, *G. galata*, Lindl., is also Brazilian. The flowers of the latter species have the segments narrower, green stained with a little purple, and the lip indistinctly banded with the same colour. Lindley remarks that the petals are much larger than the dorsal sepal, beneath which they are so placed as to resemble a helmet overshadowing the lip. *W. B.*

VANDA CATHCARTI.

This plant is figured in the *Botanical Magazine*, t. 5845, and we learn from the same source that in its native home (the Himalayas) it is usually found growing best in the immediate vicinity of waterfalls. This information affords us the key to its cultivation, and by closely imitating the natural conditions under which it is found its refractory tendencies might, in a great measure, be overcome. Indeed, I think, from what I know of the plant, there is no difficulty in growing and flowering it, provided a position suited to its requirements is allotted to it, which, from what has just been stated, points to a moist one with not too much direct sunshine. Our plant is trained against the back wall and partly over the water tank in a small stove, where the temperature during winter is about 55°–60°, and the wall always more or less damp from the moisture arising from the tank.

This position seems to suit it admirably—as it grows freely and flowers annually about this time, and is at present in flower. That the proper points of its management are attained, is shown by the bottom and side breaks flowering, but which we have been unable to flower in a small state when detached from the parent plant. Moreover, the old plant appears to suffer injury if it be shortened, and trimmed in the manner that is practised on some of the other species of *Vanda*. But it now seems more than doubtful whether this plant is a *Vanda*. Professor Reichenbach referred it to *Esmeralda*, and in the *Genera Plantarum* it is placed with *Arachnanthe*. Yet probably Lindley's name of *Vanda*, is just as good as any other for our purpose. The flowers are very striking, and remarkable. The sepals are quite an inch broad and rather larger than the petals, but both are of the same colour, elliptic in form and very bluntly pointed, overlapping each other towards the base. The ground colour is yellow; but it is so thickly marked with transverse reddish-brown lines that the latter colour is most conspicuous. The labellum, owing to its hinge-like mechanism of attachment to the base of the column, and its peculiar shape, is exceedingly striking; it is white, with two red lines running lengthwise; there are also bright red lines and spots round the cavity at the base. In shape the whole thing is not unlike a grass edging-iron with its centre pressed up, and the edges, which are yellow, sharply upturned all round. The flowers measure about 4 inches over, have a highly polished and massive appearance about them. *F. Ross*.

CYPRIPEDIUM SPICERIANUM MAGNIFICUM.

This variety promises to be very useful as a winter flowering plant when more plentiful. I lately saw a fine batch of it in flower, and also a quantity of

healthy young seedling plants, at Captain Vipan's, Stibington Hall, near Wansford. Mr. Milne, the gardener, had also a fine specimen of *C. insignis* with twenty-eight flowers open, and a very good variety of *Lælia autumnalis* with flowers 5 inches across. *W. H. Divers.*

LÆLIA ANCEPS GRANDIFLORA.

The accompanying illustration (fig. 17), from a photograph, of a fine plant in the possession of T. S. Timmis, Esq., Liverpool, well represents in its best aspect this beautiful Orchid, which with its white and newly introduced varieties, has of late years so far enriched our Orchid collections that in many places either a separate house or considerable space is given to them. The variety *grandiflora* has of late been sent us from several correspondents round Liverpool, who had acquired their specimens out of the *L. anceps* "Morada" importation of the Liverpool Horticultural Company, Garston, Liverpool. The *Morada* variety is characterised by fine size and form of flower, dwarfness and neat arrangement of the flower-spikes, and more particularly by the breadth of the front lobe of its rich purplish-crimson labellum, which may be seen even in the necessarily reduced proportions of the engraving. The plant illustrated was fully described in our issue of December 24, 1887, p. 788.

ONCIDIUM SPLENDIDUM.

Mr. Sander sends us a flower of this species, received from the gardens of Baron Edmond de Rothschild, of Armauvilliers, near Paris. In 1871, when we had occasion to write of this species, it was rare, and it still remains so. Our original figure, taken from a plant of Lord Londesborough's, almost exactly reproduces the flower before us. The sepals and petals are recurved, undulate, pale yellow, with broad chestnut-brown blotches. The lip is clear canary-yellow with a wedge-shaped stalk, and a rounded sub-cordate limb. Projecting from the centre of the stalk of the limb are three straight keels, of which the central is much the longest; the column is thick and short, and furnished on either side at the top with an ear-shaped process, white, with a few purplish spots, and greatly resembling the head-dress such as many of the Dutch or Flemish ladies of Rembrandt's time affected. Quite in the interior of the flower are two yellow tooth-like processes, apparently proceeding from the base of the lip, but quite concealed from view till the flower is cut open. (See fig. 18.)

VANOA CÆRULEA.

The following note has come to hand since the issue of the representation at p. 41, January 14:—"The photograph shows a mass of *V. cœrulea*, some of the spikes having as many as seventeen flowers on them. The plants have an exquisite effect when mixed with Ferns and other ornamental plants. They have been grown in rather a dry position, with plenty of light and air, the roots clinging to the bare benches, for they do not seem to relish any sand, or any other material on the benches, that would hold the moisture about the roots too long." *G. S., Rochester, U.S.*

THE BULB GARDEN.

FREESIA CULTIVATION.

THERE is no reason why any one with an intermediate-house should not succeed in growing this charming flower, if only its natural requirements be followed. It is a semi-aquatic plant from the streams of the Cape of Good Hope and Natal, therefore should be liberally supplied with water, and kept growing the greater part of the year, and never dried off entirely. To see some fine examples of such treatment a visit to Mr. Bartlett, of Earlhams Hall, Norwich, would well repay any one. Some few years since some thirty bulbs were sent by a friend from the Cape, and which were potted in a 6-inch pot, and as the plants grew were potted on from time to time as the pots became full of roots, till now they are a perfect

picture to behold, being 3 feet high, and a sheet of bloom. It is a great mistake to treat them as many do, by being satisfied with one spike of bloom; for, like *Ixias* and *Gladiolus*, *Freesias* throw off bulblets, which in their turn produce spikes of bloom.

Now is as good a time as any for potting the bulbs, as large importations have just arrived in England from the Cape. If potted now, and treated as above, they will produce a quantity of flowers, and will well repay any one who requires a quantity of pure white sweet-scented flowers all through the year. On p. 83, I observe, E. Jenkins states that they want water sparingly at all times, which statement, I think, is erroneous, semi-aquatic plants naturally requiring plenty of water at all times. Mr. Bartlett gives his plants water freely several times a day, and hence his success, and besides, grows them over a tank of water. The soil most suited is, as Mr. Jenkins says, an equal quantity of good fibrous loam and peat, with a free admixture of sand and plenty of drainage. The best temperature is from 55° to 60°. *J. G. Hill.*

RAISING NEW VARIETIES OF AMARYLLIS.

Since the remarks by me on *Hippeastrum* were published at p. 56, I have thought that something more might be added on hybridising and raising of seedlings that might be useful. In less than a month the first flowers will be open, and the interesting process of crossing may be commenced. I have stated that the attempt to cross *Sprekelia* with *Hippeastrum* was a failure; and as far as my experience extends with the best named varieties of the *H. Leopoldii* type, it is very difficult to obtain seeds from them. The variety *John Neal* is, perhaps, the grandest garden variety of this type, and one that might be expected to reproduce handsome progeny; but hitherto the difficulty has consisted in obtaining good seeds, and whether this variety is fertilised by its own or by some other pollen, the result is the same. The flowers will show that they have been fertilised, and the pods will swell rapidly up to a certain point, when they shrink up, and there are no results. Except in several special instances, it is not desirable to save seeds from flowers crossed with their own pollen only, as I proved when I tried the experiment with that handsome variety, *Empress of India*, when it was first introduced to cultivation, and raised 700 plants from one umbel of flowers. There were five pods of seeds only. The result of this experiment was a large number of plants not differing materially from the parent; a few of them were better, but by far the larger proportion were inferior. The best results are obtained by cross-breeding, and I would rather have fifty plants raised from seeds that had been obtained by a judicious selection of parents than 500 from self-fertilised flowers. It has been stated frequently by experimentalists, that pollen from a distinct species, applied to a garden variety, is more potent than if its own pollen were employed. This is so in some instances, but not invariably. I have sometimes found the reverse to be the case. Dean Herbert, writing in the *Journal of the Horticultural Society*, in 1847, "On Hybridisation amongst Vegetables," seems very positive in the affirmative. He says that "the observation of several years enables me now to say that this remarkable fact is almost invariable, and that although the hybrids in this genus (*Hippeastrum*) are capable of bearing seed by their own pollen, the admission of the pollen of another cross-bred plant of the same genus (however complicated the cross) to any one flower of the umbel, is almost sure to check the fructification of the others, so the excision of the anthers in such case is quite superfluous, the difficulty being to get the individuals to fertilise their own germens." Herbert, in his very interesting paper verifies this statement by instances which came under his own observation; but doubtless many growers could give instances of plants of this genus producing flowers on which their own pollen was more potent than that taken from flowers of another species or variety. In fact Herbert himself states that the original *H.*

Johnsoni was in itself "capable of reproducing itself from seeds," and "A bulb of *H. solandriflorum*, Johnson, of which all the flowers now set by their own pollen, produced seed vigorously from all of them."

I would like to remark here that the species, *H. solandriflorum*, in two varieties (see *Bot. Mag.*, t. 2573 and 3771), as they were grown by Herbert at Spofforth, are likely to make quite a new class. They are grown in the collection of Messrs. Veitch, at Chelsea, and have been crossed there with some of their best garden varieties. The produce has already flowered in their Chelsea nursery. It may be either used as a seed or pollen bearer, and long-tubed flowers of rich and varied colours may be produced. They would be quite different in character from the produce of *H. pardinum* and *H. Leopoldii* species which have scarcely any tube. It will not be difficult to cross any species or variety of *Hippeastrum* with each other. The anthers of the flower intended to produce seeds can easily be removed with the fingers before the pollen-cases burst; that is about two days before the flowers are fully open. The flower must then be left until the petals have reached their full expansion. The pollen can very easily be applied to the stigma with a small camel's-hair brush. I perform the operation once a day until the flower fades, as one cannot be sure that the pollen on the one hand and the stigma of the other flower may be productive on the day of the first application, besides the seed-pods may start to swell, and give the cultivator the idea that they are likely to be full of seeds; but they may only reach a certain stage, and then suddenly collapse. The flowers ought not to be much shaded during the period of fructification, and a moderately dry, buoyant atmosphere ought to be maintained.

I sow the seed as soon as it is ripe, placing it in a hothouse with or without bottom-heat; but it will vegetate most freely with a bottom-heat of about 85°. The doubtful seeds, which may probably produce the best flowers, will vegetate in a bottom-heat, and might not do so without it. I prick out the plants in three weeks after they appear above ground—about a dozen in a 5-inch pot, where they grow freely up to mid-winter, when they are repotted and started with the others. *J. Douglas.*

CULTURAL MEMORANDA.

CYPERUS ALTERNIFOLIUS.

THIS almost indispensable decorative plant and the variegated form of it are easily increased by division of the roots, or by inserting medium-sized tops in small pots filled with light soil with a surfacing of silver-sand, and plunging them in a good bottom-heat. Plants of dwarfer habit than could be obtained by division of the roots will be secured within a month or six weeks from the time of putting in the tops, which should rest on the surface of the soil. The plant may also be readily propagated by placing the tops with an inch of stem attached in pans of water in a stove or Cucumber-house, potting them up after they have sent up several little plants in a mixture of peat and loam, and a sprinkling of sand. The plants should be kept moist at the roots. They will thrive in any temperature between 55° and 85°. The variegated form should be potted in all heat, giving only sufficient sand to keep it porous, and any green stems that appear—which they not unfrequently do—should be removed forthwith.

ECRHORHIA JACQUINI FLORA.

The long sprays of scarlet flower bracts furnished with long narrow green leaves, which this erect-growing stove plant freely produces during the winter months render it a desirable and effective plant. Cuttings taken off now and inserted in small pots filled with sandy mould, watered, and placed under a bell-glass or hand-light in a stove or Cucumber-house will soon root. They should then be potted singly into small 60-size pots in a mixture of loam and peat, with a dash of silver-sand added,

putting the plants back in heat in a position near the glass, and as soon as they have made fresh growth pinch the points out, repeating the operation a week or two after they have been shifted into 3-inch and 4-inch pots respectively to make them branch, but not after they have been put into their flowering (6-inch) pots. The growths should be trained up under the glass during the summer and early autumn months in order to get them properly ripened, giving water at the roots when required. During the last two weeks of September and throughout October the plants should be rested a little by putting them in an intermediate-house, returning them to the stove or forcing-house early in November. *H. W. Ward.*

CISSUS DISCOLOR.

This stove climber is a good subject for a basket or hanging vase, for covering a wall, or as plants in a pot trained over some form of trellis. It makes a handsome specimen, and as such is frequently met with at summer horticultural shows. Small plants of it, alternating with plants of *Panicum variegatum* at the sides of the staging or kerb in the plant stove, are a tasteful arrangement. It is easily increased by cuttings taken from the young growth and put into small pots filled with sandy peat and put into heat. They may be potted off singly when rooted, or a cutting pot may be shifted into a larger pot and thus grown on.

FICUS ELASTICA.

Cuttings of this plant taken now and put in singly in 3-inch pots filled with sandy soil in a bottom-heat of 85°, and kept moderately close, will root in a month. Shift when the roots touch the side, and grow on in a hotbed for a month, when they may be taken to the stove or warm greenhouse and placed near the glass. They will make nice useful plants by the end of next summer. The wood chosen for cuttings should be ripe, one or more years old; soft growth is of little value for the purpose. Tie up the leaves to a stick whilst in the cutting bed, to prevent injury to them. Plunged in a bed of tan or leaves in a pit and afforded plenty of room and but little shading the *Ficus* makes fine robust specimens. *F. australis* is an almost equally good species, and is hardier than *F. elastica*. *H. W. Ward.*

PLAN OF GARDEN AT DUNHAM MASSEY.

The plan (fig. 19) of a Cheshire garden is one that was proposed by Mr. John Shaw, of Bowdon, a landscape gardener of established repute. The place is the property of W. Bery, Esq., Dunham Massey. We think that, as regards the boundary screens, and groups to secure diversity, the arrangements are well adapted to the purposes intended to be fulfilled, but the floral decorations of the garden appear to be inadequately provided for, as, with the exception of the geometrical parterre in front of the house, no other provision seems made for the cultivation of flowering plants in the open air, unless that be done in the kitchen garden. We note, too, that the vineries have half-face round to the east, thereby robbing them in the afternoon of some direct sunlight. Mr. Shaw has kindly furnished us with the following particulars:—

The site chosen for the house and grounds is on the slope of a hill commanding extensive views south to west over the well-wooded counties of Cheshire and Lancashire. It is also comfortably backed up and screened from the north and east winds by the old woods and park of Dunham. The main entrance is direct from the Knutsford road, with suitable back entrance and other convenient outlets to interesting points of surrounding scenery. The laying out of the grounds, it will be seen, is in the natural style, as being best adapted to the situation and the natural features of the vicinity. The terrace, flower garden, and immediate surroundings of the house are subordinate to it, but, with the exception of the parts to be used for lawn tennis and other games which are level, the

general surface is considerably undulated, with easy slopes pleasantly diversified by promontories for views and recesses for privacy, shade, and shelter.

The lawn is spacious for a place of this kind, and unspoiled by the objectionable system of cutting up into flower-beds or the spotting over with trees, which is carried to too great an extreme in some gardens.

The kitchen garden, of rather under half an acre in extent, is situated conveniently to the stables, and pretty well screened from the pleasure ground, without being unduly shaded. The walls will be utilised for growing fruit trees.

The conservatory is attached to the house, but the vineries and forcing-houses are as indicated on the plan. The house, stables, summer-house, and forcing-houses are placed not only for convenience, but are so diversified in their construction that each forms a feature in harmony with its neighbouring objects. As the situation and soil are in every way

this purpose the earliest forced plants are not suitable, being too much weakened through hard forcing; but those plants are the best which are turned out from the middle of April to early in May. After being placed in a sheltered situation for a short time and well attended to as regards watering they are planted in their permanent quarters in the garden. Care must be taken that the soil is placed firmly round the ball, and that the plants are well moistened previous to being planted. Towards the end of June these plants should afford a fair supply of sturdy runners which I prefer to runners from the previous year's plantations. As soon as runners are procurable they are placed in small pots, and are not detached from the parent plant until well rooted. When detached they are placed in a position facing west, where they remain until they show unmistakable signs of active growth. Where thousands of plants are grown it is well to layer a few hundreds more than are wanted for potting as, there will

FIG. 18.—ONCIDIUM TIGRINUM VAR. SPLENDENS. (SEE P. 107.)

suitable for the growth of the generality of most species of trees and shrubs, only such will be planted as will afford shade, shelter, and pictorial effect.

STRAWBERRY FORCING.

PREPARATION OF THE PLANTS.—From this time onwards until early Grapes, Peaches, &c. are ripe, there is no fruit of more importance than the Strawberry, and its successful cultivation should be such as to afford ripe fruit in quantities without a break from the middle of February until ripe fruit can be picked out-of-doors. To do this entails much forethought and painstaking skill. There are various ways of growing and preparing the plants for forcing, and every experienced grower will adopt that system which he has found in practice to answer his purpose the best; that is what I have done, and thinking that the practice may be of interest to some of your readers I furnish the following points of it. It is my custom to preserve as many of the forced plants annually as are wanted to plant a quarter in the garden. For

generally be a few weak and badly rooted plants which must be thrown away or put on one side for the reserve border in the garden. The pots I use are termed 6-inch, but they measure rather more; all are made scrupulously clean before being used.

POTTING AND SUMMER TREATMENT.

The soil used in potting is composed of three parts fibry loam, with most of the fine sifted out, and one part old Mushroom-bed manure, with a liberal addition of bone-dust and soot. Only one good crock and a few small ones are used (these must also be clean); these are covered with fibry turf afterwards sprinkled with soot to prevent the ingress of worms. In potting it is almost impossible to press the soil too firmly in the pot, and the crown of the plant should be a trifle higher than the surface of the soil. After potting the plants should be placed together as thickly as possible in a sunny position and should remain here until they have made considerable progress in growth, when they must be afforded more room and arranged in beds of five or six rows with paths between the beds for watering, weeding, and keeping runners down.

As soon as the pots are fairly full of roots, the plants receive an occasional dusting of soot, and this is the only stimulant they receive whilst growing. Some of the varieties are prone to form duplicate crowns, these should be reduced to one or two as soon as perceived.

The plants should remain out-of-doors to as late a

WATERING.

There is no duty so important in connection with the successful growth of pot Strawberries as that of watering; for you may observe every detail necessary to secure good results, but if you fail in the matter of careful and timely watering all other labour will count for nought, and failure will be

well, and his superior can say that his plants have not suffered at any time from the want of water, or from the ravages of spider, then I should mark that man, and feel much disappointed if he did not succeed in life.

THE EARLIEST CROPS.

To have ripe fruit about Valentine's Day, which is

FIG. 19.—PLAN OF GARDEN AT DUNHAM MASSEY. (SEE P. 108.)

date as possible in the autumn; mine are left out until there is danger of frost cracking the pots. The plants are best wintered in cold frames, the pots plunged in leaves to the rim. If wintered in fruit-houses, as is common in most gardens, the plants should never be permitted to suffer from want of water at the roots, and a good syringing overhead once a week through the winter tends to keep the plants fresher and in better health than when the foliage is allowed to become too dry.

sure to follow; therefore let me urge this truth with importunity on the minds of young gardeners who may have charge of a valuable stock of these plants, never to permit them to suffer from want of water at any period of their growth, and especially after the plants are placed under glass for forcing. To have charge of five or six hundred plants in full swing on dry shelves in lofty houses from March to the end of May is as severe a test of the mettle of a young gardener as I could imagine. If he acquits himself

the time we usually commence to pick it, it will be necessary to introduce the first batch of plants into heat a day or two after Christmas. The means most favourable for starting the plants into growth I have found to be a pit with a thick bed of Oak or Chestnut leaves, which will afford a bottom-heat of 70°, and the top-heat should be kept at about 50°; the plants must be arranged close to the glass. As soon as the flower-buds can be discerned the plants are removed to a warmer temperature—generally a shelf

near the glass in the Melon or Cucumber-house, where they remain until the flowers are on the point of expanding, when they are again removed into a house which has a warm current of dry air passing through it, and where they receive daily attention to fertilisation. At this season of the year this is an important point, as is shown by the many deformed and useless fruit we observe on plants not carefully attended to in this matter.

As soon as the fruit is set the plants are again placed in more heat in a light position near the glass, where they soon swell and mature a crop of fruit, which, when well finished, afford as genuine a pleasure to a grower as the far superior crops do later on. Some may object to the labour of shifting the plants from one position to another; but when it is a question of success or non-success, the slight additional work is of no moment.

As the season advances the attention to fertilisation will not be so necessary, but all through the matter must be borne in mind, as it is impossible to have satisfactory crops with imperfect fertilisation.

SUCCESSIONS.

Once a week during the season the plants should be overhauled—those which have done fruiting taken out, and their places immediately filled up with the forwardest of the plants with set fruit coming on in cooler houses. Those setting must be looked over, and the fruit thinned, reserving eight on each plant. Any "blind" or imperfectly fertilised plants should be thrown away, and a succession brought in from the cold pits. If this work is readily attended to once a week, and sometimes oftener, there need be no break in the supply of ripe fruit for dessert; but if only attended to in a hap-hazard sort of way, then only a fitful and unsatisfactory supply is obtained. A liberal use of the syringe is beneficial to Strawberries in pots at all stages of growth during forcing (excepting when in bloom), and absolutely necessary in hot weather when the plants are grown on shelves in fruit-houses, if spider is to be kept in check.

The forcing of Strawberries is made much easier and more simple where a house is provided for the purpose in different sections, although I have seen better fruit on shelves in fruit-houses than I have ever seen in houses exclusively devoted to their growth.

It is a good plan, where a cold pit can be spared, to plant it with Strawberries; most excellent crops are grown in this way, and often prove valuable in giving a supply at the end of the first season, and before the out-of-door fruit is in.

VARIETIES TO FORCE.

The question, Which are the best varieties to grow? is an important one to the Strawberry grower, and one on which many opposite opinions are held. As a first early variety some growers employ Black Prince, and others Keen's Seedling, and Vicomtesse H. de Thury, and some the latest favourite, Pauline; all these I have grown extensively, but have discarded in favour of La Grosse Sucrée, which in my estimation is the best early Strawberry in existence; to be followed by Keen's Seedling, President, Sir C. Napier, Sir J. Paxton, Dr. Hogg, and a few Marguerite for size. *O. T. C.*

FLORISTS' FLOWERS.

PRIMULAS.

Choice species, Alpine and Himalayan, are treated very much like Auriculas, both as regards the treatment of seedlings and of old plants. Most of them are of more vigorous growth, and also grown more rapidly. The largest sized pots we use for Auriculas would be about $4\frac{1}{2}$ inches in diameter, whereas some of the Himalayan Primulas would require 8-inch pots after one year's growth. Some of the most vigorous are *P. prolifera*, *P. purpurea* (not the *P. purpurea* of Royle), *P. sikkimensis*, *P. luteola*, *P. rosea*, and a few others. The alpine species are, as

a rule, more dwarf in habit, and if large pots are used for them the plants are not likely to do so well. They all require to be placed in an open, airy position. Damp close frames, or too much water, cause many of them to rot off at the neck. If necessary, any of them requiring to be surface-dressed should be seen to now. All of them must be made thoroughly clean. In addition to the leaves being attacked by greenfly, and the roots with woolly aphid, that more insidious pest, red-spider, is very troublesome; it will sometimes altogether destroy the leaves of such species as those of the *P. purpurea* type.

THE POLYANTHUS.

These are the most difficult plants to manage of any varieties or species of the great Primula family. If we could produce first-class varieties easily from seeds the work would be easy enough; but I grow annually numbers of plants from seeds of the best varieties, and have not yet raised anything to nearly equal George IV., Lancer, Exile, Prince Regent, Cheshire Favourite—or, indeed, any others of the old beauties of long ago. Amongst moderns Mr. Barlow has made some of the best hits in the way of seedling raising, and Sanderson's Naxara is very distinct, and equal to the best. The plants are now in a frame near the glass, treated as the Auriculas are, but they require rather more water at the roots.

THE CARNATION AND PICOTEES.

Already we are preparing the compost for potting the entire collection of plants in February, that being the month in which the work is usually done here, although we sometimes go into the early days of March with it. The material used is loam four parts, leaf-mould one part, and decayed stable-manure one part, with a portion of sharp sand added to it, and all the different materials are well mixed. This compost is better for being in a heap at least six weeks before it is used. As regards the sizes of pots, we use 7 to 8 $\frac{1}{2}$ inch, and find them quite large enough, the layers rooting better in the autumn, when the small pots are used, than was the case formerly, when much larger ones were used. The compost being prepared, and placed where it cannot be saturated by rain, it is ready for use when required. Before commencing operations let the pots be cleaned and well crocked, some tough fibre, free from loose particles of earth, being placed over the crocks, a little light flaky manure being mixed with it. All our plants were in large and small 60-sized pots; and in transferring them from these into the pots in which they are to flower we are very careful not to cause damage to the roots, and my object in potting the plants thus early is to give them a better chance to recover from the shift. However careful one may be in repotting a plant, it is certain that some roots will be damaged, and this is easier to be repaired about the end of February than later. I do not ram in the compost too firmly, but it is better that it should be made firm with the fingers, so that no spaces are left round the old ball. It was an old custom to place the pots containing newly potted plants out-of-doors as the work proceeded. If that is still anywhere preserved, early potting will not answer, and the operation had better be delayed until the middle of March; but even then there is danger, as I well remember. Encouraged by the mild weather, I placed the plants out-of-doors, but before the work was completed the wind had changed to the east, and snow fell heavily. This taught me a lesson for my future guidance, and now the plants are put into frames as they are potted, and no water given for two or three weeks; this latter depends, of course, on the kind of weather experienced; some seasons they are not watered for six weeks after being repotted. Frost may set in, and continued cold weather, but the plants will be all right if they are kept dry—they do not mind the cold.

The whole collection out-of-doors in beds and borders looks very promising, and, so far, they have required no attention. We shall first remove the dead and decaying leaves from the plants, pull out the weeds with the fingers, and then stir the surface

of the ground with a hoe. I tried an experiment of late planting this year. The rooted layers were not taken off until the end of November, and they were at once planted out in the open. I hope they will succeed even better than the earlier planted ones. *J. Douglas.*

"REN" CARNATIONS.

Mr. M. Rowan, of Clapham, has recently made known a curious circumstance affecting "ren" flowers of Carnations. Two plants, sports in 1886 from John Harland, crimson bizarre, with pink grounds and maroon markings, took singular departures during 1887. One returned to the pure white ground and beautiful colours of the original, while the companion plant subsided further into a deep purple self. The vagaries in the way of sportiveness in flowers is something remarkable, and these are cases in point.

THE DRY SUMMER AND CARNATIONS AND PICOTEES.

Mr. Tom Lord, of Todmorden, a well-known grower and exhibitor of these flowers, makes the interesting statement that, though the season of 1887 commenced unkindly, the development of the plants by the end of the summer was most satisfactory. The appearance of the weaker growing varieties, Rob Roy, R.F.; Muriel, H.P.P.; Esther, Minnie, and Lady Louisa H. Rose, P.S., is such that good blooms may be expected.

PLANTS AND THEIR CULTURE.

PROPAGATION.—To be an adept in the art of increasing plants the gardener must be a good plantsman, because patience and careful attention to the individual requirements of the plants are the chief factors that are essential to success. The operation is very much simplified when there is a special house or pit for the purpose, but much may be accomplished without these helps, and there are few gardens in which suitable places could not be made out of existing structures. In the case of tropical plants a warm sheltered corner should be selected, such as where, from some cause or other, there are a greater number of hot-water pipes. But whatever position be selected, and having decided on the size, enclose it with boards so that it can be filled with material to absorb the heat from the pipes, and to plunge the cuttings in. This material may be either leaves, tan, coal-ashes sifted finely, cocoa-nut fibre refuse, or sawdust; the last-named two are, I think, the best, and in point of cleanliness I prefer the sawdust—I also find that sawdust is a capital substance in which to root many things. A frame is placed on this prepared bed, and in doing this try if possible to get the back or highest part of the frame on that side which would be the sunny side, the object being to get a maximum of light without having to use much shading, as much shading seems to retard the rooting process in cuttings, and undoubtedly weakens them. In all these arrangements for the propagation of plants the principle is the same, viz., to maintain the balance between evaporation and absorption; thus, when the cuttings lose water in excess of what they are able to take up they wither, and as plumpness is a necessary condition of growth none can take place until the necessary degree of distension is regained. It is, therefore, proper never to let cuttings flag. See that the bottom-heat does not get too strong, which is an evil most to be guarded against at first. A strong bottom-heat will cause cuttings to flag even when sufficient shade and moisture are afforded.

Where there is much furnishing or table decoration to be done a large batch of suitable things put in at the present season become well rooted and fit to pot on just in time to get the full benefit of the bright days of spring, thus admitting of early maturation of growth. And again, should the object be to grow them into specimens we cannot over-rate the advantages of an early start. In taking the cuttings choose large healthy pieces, especially when the cuttings are those of Crotons, *Eranthemums*, and *Acalyphas*; there are, however, plants which, when required in a small state, are best when grown up from small cuttings and eyes, such as *Cyanophyllum* and *Cordylines*.

In putting in the cuttings use sandy soil, as this,

THE FLOWER GARDEN.

BEDDING PLANTS.—Plants for summer bedding should receive timely attention. Look over autumn-rooted Pelargoniums in store pots and boxes, taking out dead ones and removing mouldy and decaying leaves, and ventilate freely on fine sunny days. In watering, exercise caution for the present, and avoid extremes either way. Examine old plants, cutting out all dead shoots. These plants will furnish cuttings to replace losses amongst the autumn-struck stock, and if taken off now, inserted singly in small pots, and placed in a little heat, they will soon take root, and make serviceable stuff in time for planting out. Stock plants of *Alternantheras*, *Iresines*, *Coleus*, *Lobelias*, *Tropaeolums*, *Ageratums*, and *Verbenas*, should also be seen to, and where doubts are entertained regarding the quantity of cuttings required, push on in more heat, placing them on shelves near to the glass.

Frame Ground.—Cold frames containing shrubby *Calceolarias*, young stocks of perennials, *Violets*, *Echeverias*, &c., will require occasional examination by way of cleaning, and stirring the surface soil with a pointed stick, to render all clean and sweet. Ventilate freely on all favourable occasions, the object being, for the present, not to excite the plants into what would be premature growth. See that the means to exclude frost are in readiness, and should the plants get frozen thaw them gradually, and shade from sunshine for a few days; timely precautions, however, ought to be taken to avoid an occurrence of this nature.

Seed Sowing.—Seed of tuberous-rooted *Begonias* may be sown, using shallow pans with plenty of drainage and a compost of finely sifted loam, peat, leaf-mould, and sand; water the soil before sowing and let the seed remain on the surface and cover the pans with a pane of glass—some would use a tile. The following seeds of subtropical bedding plants may be sown without delay, viz., *Cannas*, *Ferdinandia emines*, *Acacia lophantha*, *Solanum giganteum*, *S. robustum*, *S. pyracanthum*, *S. Warscewiczii*, *S. marginatum*, *S. laciniatum*, *Wigandia caracasana*, *Melanthus major*, and *Acanthus latifolius*. Place the seed-pans in a temperature of 70° to 75°, and when large enough prick out the seedlings into other pans, or singly into thumb-pots, shifting on into larger pots as they require more root-space. A compost of loam, peat, leaf-mould and silver-sand, with good drainage, will suit such plants. *J. Horsfield, Heytesbury.*

THE HARDY FRUIT GARDEN.

THE PRUNING OF BUSH FRUITS.—All these should now be pruned without delay. Before pruning Gooseberries, the purposes for which the fruit is required should be taken into consideration. For instance, the bushes from which the fruit is gathered in a green state may have the wood left rather thickly, while those which are desired to produce fine fruit for dessert will require more thinning, and he side shoots to be spurred in to two buds. It is always a good plan to leave a few well-placed young shoots, so that one or two of the oldest and undermost branches may be removed annually.

Currant bushes of the red and white varieties, if well established, should have the side shoots spurred in to three buds, and leaving 3 to 6 inches of young wood, according to needs and position, on the ends of leading shoots.

In pruning black Currants which do not require any stopping, merely remove some of the oldest and worst placed wood. If this matter is properly attended to yearly, the trees will always be furnished with vigorous bearing wood, which will bear fruit of the finest quality in large quantities. After Gooseberry and Currant trees are pruned (should they have been attacked last year with caterpillars) take a hoe and scrape the soil away to the depth of 2 or 3 inches from under the bushes and as far as the branches extend. Then on the exposed surface apply a good dressing of freshly-slaked lime—this will be found a good preventative. The soil that is scraped away should either be dug in deeply between the bushes, or, better, taken away and buried, as it contains the small brown cocoons from which the sawfly issues in the spring. This advice does not apply to black Currants.

Gooseberry and Currant Cuttings.—Should it be

desired to increase the stock of any particular variety, and the cuttings are not yet made, select medium-sized shoots: no time should be lost in doing so. If small birds attack the buds of Gooseberries, it may help to keep them away to dust the bushes well with a mixture of lime and soot; but this is not always successful, and netting the bushes or shooting the predators may become imperative.

Raspberries.—If these were properly thinned last autumn, but little will remain to be done beyond topping the shoots to the required height. Leave six canes to a stool, use fresh stakes if found necessary, and fasten the canes to the same with tarred twine, or Willow twigs. The framework from which the nets are suspended to keep birds from the fruit had better be looked to, and repaired if it be found necessary, as time for this kind of work can be better afforded now than when the season is more advanced. Autumn-fruiting Raspberries, which bear on the current year's growth must be pruned close to the ground, and if fine fruit is wanted give a liberal dressing of manure. *A. Ward, Stoke Edith Gardens, Hereford.*

FRUITS UNDER GLASS.

MELON-HOUSE.—Melons which are planted on mounds should receive a steady night temperature of 70° to 75° at this season of the year, and it will be found advisable to augment the bottom-heat with warm leaves, the warmth from these being more genial than that from hot-water apparatus alone. Sowing Melon seeds in small pots is a complete waste of time, tending to weaken the constitution of the plants, and to predispose them to attacks of red-spider and thrips. It is better to make up a good bed of warm leaves in the houses, keeping it as close to the glass as possible; on this place tiny heaps of nice sharp light soil, and in each heap place two or more seeds. They will germinate as quickly and grow more robustly than those grown in pots. I have succeeded in rearing young Melons this way when the pot system has signally failed.

Cucumbers.—Plants which have fruited up to the present time will be greatly benefited by slight top-dressings of nice light soil and a little Vioce manure put over their roots; if put on in thickness of about an inch and a half it will be quite sufficient, each time the roots appear on the surface. These plants should not be stopped so closely as summer fruiters. Prepare another division for early sowing, if not already done; see that the structure is scrupulously clean, and make up a bed of warm leaves, on which place small mounds of two parts leaf-mould, and one part spent Mushroom-bed and fibry loam; into each of these place a couple of seeds. Maintain a generally humid atmosphere by frequently sprinkling the paths and walls, and let the temperature be about 65° to 70°. *W. M. Vallie, Luton Ho.*

THE KITCHEN GARDEN.

FORCING-PITS.—If the fermenting material has been prepared as was advised a fortnight ago, it should now be ready to make up into hotbeds for early Potatos. In making the bed, pack all the material firmly together; put a thickness of about 1 foot of rich light soil on the top, and as soon as this is warm, plant the Potatos that have been previously started into growth in boxes, making the rows 15 inches apart, and putting the sets 12 inches apart in the rows. If room be scarce, a few Radish seeds may be scattered thinly over the top, and lightly covered in, but these as a rule are much better when sown by themselves. Early Milan Turnip and Early Nantes Carrots should be sown now in hotbed frames.

Chicory should be taken up, and the roots placed rather closely together in a Mushroom-house, or any similar position that is warm, moist, and dark, about a fortnight before being required for use. Any Lettuces or Endives still remaining outside should be taken up in mild weather, and be re-planted in a cold pit where they can be prepared for use as required. Endive is quickly and easily blanched if planted in boxes 4 inches deep, and put in the Mushroom-house, and is then very tender. If Onions are likely to be scarce toward the end of the season, any that may start into growth now should be planted out, such will be useful for pulling green before the Tripoli varieties are ready. *W. H. Divers, Ketton Hall.*

being very porous tends to prevent the loss of cuttings from damping off, and the smaller the pots are the better, provided they contain enough soil to hold the cuttings firmly in position, neglect on this point is the cause of much loss. I always find it better, when the cutting is large, to fix it to a small stake, and also to tie up the leaves. This last operation, while assisting in steadying the cutting, also prevents the leaves from being damaged so much as they often are when fully spread out; space is likewise economised. Finally, water them, and plunge the pots in the propagating frame, and maintain a constant degree of humidity and warmth about them, with as little variation as possible. Strict attention to the last named points will greatly minimise the chances of failure.

Potting Plants.—With the beginning of February will show signs of moving, therefore the general potting should be no longer delayed. In order that it may go on rapidly after commencing, it is well to see that all requisites are got in readiness. Loam, peat of various grades, leaf-mould, and sand, having been put under cover last month, these will now be in capital condition. The fibry and more durable portion of peat should be used for plants as the staple for such plants as *Ixoras*, *Marantas*, *Alocasias*, *Anthuriums*, &c., the finer portion being suitable for mixing with loam in potting *Dracenas*, *Eranthemums*, *Ferns*, &c. The fibry part of loam is proper material for Palms, Cycads, *Crotons*, *Dasyliions*, *Yuccas*, and *Beaucarneas*, &c. Leaf-mould should be freed from bits of decayed wood, which is apt to breed fungus in the pots. The operation itself is simple enough, and generally well understood, yet it is well to remember to use clean pots only, and to crock them with clean crocks, and not to pot a plant when it is dry at the root or when in a wet condition, but fairly moist throughout is the best state in which to pot, and, unless with strong growing or annual subjects, do not give large shifts. Disentangle the outside roots carefully, and give small shifts, and, if desired, pot again as soon as the roots reach the side of the pot. In putting the soil into the pots care should be taken to work it well in amongst the roots—always making it moderately firm, as the roots are only able to perform their proper functions when in close contact with the particles of the soil. Leave plenty of room for watering, and in finishing the operation the surface of the soil should have a nice rounded appearance, and rather higher towards the collar of the plant.

Mignonette.—Plants which have been wintering in pits or frames should have air afforded on every favourable occasion; pinch off any weak growths, and assist them with weak liquid manure. A little clear lime-water is also beneficial to the plant. If the plants are standing on a cool moist bottom, the temperature may now be kept up to about 55°. Avoid overwatering the plants. Put in fresh seeds for succession, using 48's and 32's—the sizes which are the most useful. For soil, use three parts good loam, adding rotten manure, leaf-mould, and a little sand; and either use some lime rubble in the crocks or mix some with the compost, which latter ought to be of a fairly retentive character. Sow the seeds thinly and cover lightly, thinning out to eight or ten plants, and shade from strong sun as soon as the seedlings are large enough to be handled. When 4 inches high put a small stick to each plant, keeping the plant in front of the stick. Parson's white, Golden Queen and Giant Pyramidal are varieties that will suit the most fastidious.

Calceolarias.—Those do best in pits or frames where the frost is only just kept out, and plenty of light and air afforded. Late successions should be moved into their flowering pots before there is any sign of their showing flower, as it is very little use potting after that. Having tried them in many soils, I have found them finish best in rather strong loam mixed with leaf-mould and sand. Should greenly put in an appearance syringe with weak tobacco-water, taking care to apply it on the underside of the leaves—a "crank" syringe with a rose being the best instrument for applying it.

Fuchsias.—The general stock of these should now be brought out from their winter quarters, pruned hard back, and placed where they can be occasionally syringed. An ordinary greenhouse temperature suits them best, but plants may be put into heat to afford cuttings. Pot off cuttings which have been recently struck, using light rich soil consisting of one-half loam and one-half sand and leaf-mould, or manure. Pot firmly. *F. Ross, Pendell Court.*

The Royal Horticultural Society.

THE affairs of this Society continue to occupy the attention of the horticultural world to an extent that may seem to an outsider disproportionate to their real importance. If the Society were necessarily metropolitan, and devoted exclusively to the gratification of a limited number of pleasure-seekers, or of members with personal interests to serve, this impression would be correct. But the facts are far otherwise. The decadence or the success of a purely local or personal society would be subjects of limited interest only, but in this case we have a matter of serious national importance to consider. In most foreign countries the State undertakes the supervision of all affairs of public concern, in this country it is far otherwise—private enterprise and associations of individuals constituting societies take in hand the regulation of things which concern not only themselves and their own individual requirements, but also the welfare of the nation as a whole. Those who look on the Royal Horticultural Society as a society whose chief duty it is to pass a critical judgment on a Pansy or a head of Celery, and as a means for awarding prizes to successful exhibitors of one or the other or both, take a very limited view of

the subject. It is far too much the practice to look on horticultural societies as mere associations for the gratification of individual whims and fancies, and to ignore more serious matters which lie at the root of national prosperity. The amount of capital embarked in the purely æsthetic and sentimental departments of horticulture is no doubt enormous, and far beyond the knowledge of the public in general; but this, large as it is, is as nothing compared to matters of intrinsically greater importance. We have only to look to our food supplies, the enormous amount imported, and to consider the condition of agriculture at the present time, and the circumstances under which that art is practised in this country, to realise that if any portion of the money now sent out of the country is to be retained here in future and if agriculture is to be raised from its present state of depression, such results must in a very large degree be dependent upon the teachings of the science and the adoption of the methods of horticulture. The consideration of these facts must serve as an excuse, if any be needed, for recurring again to the position of the representative horticultural society.

The Society must aim deep and it must aim high; it must serve the interests of the few and most decidedly it must cater for the interests of the many. If it fail in either direction it will deservedly sink beyond the power of redemption. The present is no time for disputing over relative trifles, such as the forms of government, still less for ventilating sectarian animosities and unworthy jealousies. If anything of permanent value is to be done it must be by the earnest advocacy of sound general principles and by resolute practice, based on the legitimate inferences to be drawn from those principles. Descending from this upper region we have to face, in the first instance, the question of finance. The events of the last few weeks are reassuring as to this matter. We have little doubt now that, once a broad general policy of usefulness be laid down, funds will be forthcoming. Former experience rather leads to the fear that such finances may be wasted or misappropriated. Let us hope that the teachings of the past will suffice to prevent any such disaster in the future.

Then as to the policy of the Society. As we have said, there is practically no difference of opinion as to what its general direction should be, points of detail offer endless opportunity for discussion, perhaps for variance of opinion, but let us, before all things, subordinate these minor matters to general principles. It is not whether this section or the other is the more important—it is not whether Mr. A. or Mr. B. is the more worthy representative—not whether this department of the Society's work is more important or less important than any other—these considerations are worthy of heed, no doubt, but at the present juncture they are, as the phrase goes, "mere matters of detail."

From weariness of spirit, from utter disappointment in some cases, from the sense of years of labour and zeal apparently thrown away in the service of the Society, there are many who say in their bitter moments, let it die. Such feelings are intelligible enough, but happily they are but transient, and no large section of the community, we are sure, wish in their calmer moments that it should do anything of the kind. Rather is there a very widespread feeling that the Society must not and shall not die. Equally determined are they that the Society shall be revolutionised—but by peaceful means, by the free will and zealous co-operation of all its members, not by the violent action of a sectarian

few. The case is one for constitutional remedies, not for the exercise of tyranny and brute force such as make peace where there is no peace.

As the case stands at present, a strong and representative outside committee has been appointed to confer with the Council, and, unless appearances are more than usually deceitful, there is every prospect of cordial co-operation between the two bodies. The outside committee is strong because it is representative. Every section of the community is represented upon it, and the most earnest desire is expressed on all sides to do good work, and rescue the Society from its present depressed state. When the annual meeting is held next month it will, we believe, be found that all reasonable expectations as to the representation of the horticultural element proper will be met. The existing Council is tied hand and foot by the charter and bye-laws, but in spite of these bonds we believe means will be found at that meeting to satisfy popular requirements without contravening the letter of the law. It is no doubt a delicate and difficult matter, but it will be done. Already such good representative men as Messrs. SMEE, VEITCH, G. PAUL, and WILKS, are secure of their seats on the new Council, and we are in a position to state that steps are being taken by the Council to secure the accession of practical gardeners. There is precedent for this in the charter, where we find that of the original members—including peers, bishops, botanists, men of science, directors of the national botanic gardens, &c.—no fewer than three gardeners were included. His Majesty, GEORGE III., out of his own "especial grace, certain knowledge, and mere motion—given and granted—that"—"our right trusty and well-beloved counsellor, Sir JOSEPH BANKS; our trusty and well-beloved WILLIAM TOWNSEND AITON [the then Director of Kew], THOMAS ANDREW KNIGHT [*salve magne nomen!*], RICHARD ANTHONY SALISBURY [an eminent botanist]; and JAMES DICKSON, THOMAS HOY, and WILLIAM SMITH, gardeners," should form part of the first Council. It would be of interest to know more about these three gardeners. This by the way: our point is that three practical gardeners were on the first Council, and it would be all the better if three more were on the new. In any case, we must make the best bread we can out of the flour that is available, and we fully believe this will be done.

So far as we can learn, the Council and the committee are at one as to the general future policy of the Society—a policy it must be remembered fought for and won in Council by Professor FOSTER and Mr. DYER in particular—they are at one as to the necessity of widened popular representation, and a lowering of the conditions of franchise; they are at one in thinking that these desirable things cannot be done under the conditions of the existing charter and bye-laws; they are one in thinking that the one and the others must eventually, and sooner rather than later, be radically changed. This revolution—for revolution it is—cannot be done in a week or a month: that is obvious to anyone who will consider the matter fairly; and hence it is not unreasonable to urge patience and trust on the part of the community. By all means, when these things are seething, let us have the fullest and freest discussion consistent with fairness and good breeding, but let us also have, when the time comes for collective action, the fullest possible concord and co-operation. To secure this, we must probably each and all be prepared to sacrifice some pet notion or project, banish personal antipathies, and muzzle, if we cannot eradicate, unworthy prejudices.

PHAIUS GRANDIFOLIUS.

GROWN AT WORKSOP MANOR.

RICHARDIA ETHIOPICA.

THE PHOTOGRAPHS BY MR. G. W. WATSON, LANE, CANING, & CO., LONDON.

So far as we can see at present, there is a very general desire to do this for the general good, and if so, success is certain.

THE GARDENERS' ORPHAN FUND.—The executive committee of the above Society met at the Caledonian Hotel, Adelphi Terrace, on the 20th inst., Mr. GEORGE DEAL presiding, there being a large attendance of members. The minutes of the previous meeting having been read, the Hon. Secretary, Mr. A. F. BARRON, announced that there had been promised or sent since the last meeting the sum of £183 11s. 6d., £139 6s. 6d. being in the form of donations, and £44 5s. as subscriptions. That the total amount promised as donations was £1084 15s., of which £869 5s. 6d. had been paid; and as annual subscriptions, £315 6s., of which sum £165 9s. 6d. had been paid. The total sum promised and paid up to date is £1400 1s., contributed by 1130 persons. Several local secretaries sent in their returns up to the end of the year, and hearty votes of thanks were passed for their valuable services, and a hope expressed that they would continue to act in this capacity. The Chairman having expressed the opinion that the dates of the meetings of the executive committee should be fixed for the year, it was resolved that the meetings take place at the Caledonian Hotel on the last Friday in each month, at 6 P.M. Suggestions having been made that contribution boxes should be provided for nurseries and other public places, into which small contributions towards the fund could be dropped, it was resolved that these be provided by the committee, and it was agreed that sample boxes should be submitted for approval at the next meeting of the committee. Several letters of inquiry were duly considered. The sub-committee appointed to sketch the course of procedure to be observed at the first election of children to the Fund in July next, and also to present drafts of the necessary documents, brought up their report, but previous to considering it the Chairman stated it was important the date of the first election should be fixed. It was unanimously resolved that the annual general meeting of subscribers to the Fund and the election of children should take place at the Cannon Street Hotel, E.C., on Friday, July 13 next. The documents submitted by the sub-committee, were, first, a form of application for candidates, which have to be sent in to the Hon. Secretary by Monday, April 23; second, a form of nomination paper, including one for those desirous of recommending the case, and the medical certificate; third, a form of advertisement and also a form of circular to local secretaries, asking for their co-operation in securing full particulars in their returns from applicants; fourth, a form of contract to be entered into by the committee with the parent, foster-parent or guardian, to whose care a child may be committed. All these documents were subjected to keen criticism, and eventually passed, and ordered to be printed for final consideration at the February meeting of the committee. A suggestion having been thrown out at the meeting at South Kensington, called to inaugurate the Fund, that something in the form of a *fête* in its aid, should be provided during the summer, Mr. W. G. HEATH submitted certain proposals on behalf of the Crystal Palace Company. Eventually it was thought best for the present year to hold a dinner in the autumn, and a sub-committee was appointed to consider the matter, and bring up recommendations. The proceedings closed with cordial votes of thanks to the election sub-committee, and to the Chairman for presiding.

THE ROYAL HORTICULTURAL SOCIETY.—Among the numerous letters we have received with reference to the Royal Horticultural Society we are glad to see one from Mr. D. T. FISH, not alone on account of the policy he advocates, but because he has had the magnanimity to put aside the memory of the frightful ingratitude that was shown to him, and the cruel insult to which he was, though without any such design, subjected. He can very well afford to do so, as everyone who remembers

the circumstances will know how fully he earned all the honour that could be paid him on that occasion. Of course the Council of the day had no intention other than that of honouring the man who had done so much for it. Its action was the result of a deplorable blunder. The real fault consisted in the non-adoption of some other means of showing its gratitude when the one originally proposed was found to be illegal. Mr. FISH's letter is very long, but we must try and make room for it on another occasion.

METROPOLITAN PUBLIC GARDENS AND PARKS.—Various important works are now being carried out or under consideration by the EARL OF MEATH'S Association. The laying out of a park at Camberwell is one of the chief works. Land to the extent of some 14 acres has been presented by a gentleman who owns a large property at Camberwell, and his offer has been accepted by the Association. The donor desires to be anonymous. It is estimated that the cost of laying out this park will amount to nearly £8000, and it is hoped that a portion of the Gardens and Pleasure Grounds (Mansion House) Fund for giving work to the unemployed will be available for the work. This new park will be near the Camberwell New Road railway station, in a populous district where there are no other public parks or gardens excepting the small Kennington Park, which has always been much too limited in area for the neighbourhood. Among other good work in progress is that of transforming into gardens the disused burial-grounds of St. Albans, Fulham; All Saints, Notting Hill; St. Alphage, Greenwich; Trinity, Poplar; and St. James, Bethnal Green; also the Tower Gardens, and Edward Square, Islington. The Association have also under consideration the laying out of the Victoria Park Cemetery, about 11 acres, as a public garden; a recreation ground (1 acre) at Parnell Road Recreation Ground at New Cross. These are some of the chief works which this Association is now engaged upon, which, when finished, will add many more open spaces of which we have still too few in London. This most useful Association deserves the support of all who sympathise with the unemployed, and also wish to see those whose lives are spent in crowded neighbourhoods enjoy the privilege of resorting to pleasant public gardens.

THE MELON-PEAR.—Readers of the gardening papers have probably seen a good deal (in print) of the so-called Melon-Pear, which, after the fashion of popular names, is neither a Melon nor a Pear, nor a cross between the two. It is the egg-shaped fruit of *Solanum guatemalense*, and is a near ally of the Egg-plant and Tree Tomato. A figure is given in the *Orchard and Garden* (January), where it is described as "lemon-yellow striped with purple, attractive in appearance, and with a spicy aroma." Its exceeding sweetness is slightly tempered with acidity, and its flavour decidedly resembles that of Musk Melon.

SIR JOSEPH HOOKER.—A portrait of this distinguished botanist is to be placed in the rooms of the Linnean Society.

LINNEAN SOCIETY.—At the usual fortnightly meeting, held on Thursday, January 19, Mr. BERRY exhibited *Ranunculus pseudo-reptans* from Shetland, and the same form after being cultivated in his garden, where it had developed into the ordinary *R. flammula*, thus showing that the former is nothing but a tiny starved form of the Lesser Spearwort. *Phaiocalanthe Sedeniana* ×, from Baron SCHRODER'S collection, sent through Messrs. JAMES VEITCH & SONS to Kew, was exhibited by Mr. ROBEY, to show the way it combines the characters of the two parent genera; also *Phalaenopsis intermedia* ×, with the two parent species, as an interesting example of a supposed natural hybrid whose parentage had at length been proved by the well known experiments of Mr. SEDEN. A paper was read by Mr. SPENCER MOORE on "The Action of Light on Chlorophyll," in which he showed the different behaviour of chlorophyll-grains during varying degrees of sunlight, from ex-

periments made during the long spell of bright weather of the past summer. The next meeting will be held on Thursday, February 2, at 8 P.M., when the following papers will be read:—1. "Ferns of Simla," by Mr. H. F. BLANDFORD; 2. "Fertilisation of *Cattleya labiata* var. *Mossiae*," by Mr. H. J. VEITCH; and 3. "Descriptions of species of *Galerucinae*," by Mr. J. BALEY.

THE OXFORD CARNATION AND PICOTEE UNION.—The annual report just issued by Mr. E. S. DODWELL, the Hon. Secretary and Treasurer, shows that the third year of the existence of the Union has been characterised by much success. There are now 256 subscribers, and the income for the year now closed amounts to £125 18s. The Union began with 110 members, and the first year's income from all sources was £70 16s. 6d. In 1886 an addition of 112 members was made, and though there were withdrawals by death, removals and other causes, the income rose to £94 17s. 6d. One interesting feature of the report is the large amount of information contributed by local secretaries bearing upon the Carnation and Picotee bloom of the past year. A balance of £20 6s. 3d. is carried over to the present year.

A GOOD INVESTMENT.—We learn that Mr. WILLIAM BULL, of King's Road, Chelsea, has just purchased from the Leatherhead collection the rare *Cyprripedium Saundersianum* for £300. It is interesting to note this at a time when there is a depression in many other things, for we hear this very plant was purchased by the recent owner in the autumn of 1883 for 50 guineas.

THE NEW PARK AT RAMSEY, ISLE OF MAN.—Mr. E. THOMAS, landscape gardener, of Town Green, Liverpool, has been awarded the first prize of £15, offered by the Ramsey Town Commissioners, for the best plan of the new Mooragh Park and lake; and Mr. E. G. REID, of Prescot, the second prize of £10. There were several competitors.

"ORCHIDS: THEIR STRUCTURE, HISTORY, AND CULTURE."—A fourth edition of Mr. LEWIS CASTLE'S book is being prepared, and the work is also being translated into French and German.

THE GREAT YORK GALA.—The schedule for 1888 is now issued, and we notice that the sum of £42 10s., as well as a special prize of £5 5s. from Messrs. BACKHOUSE & SON, is offered for Orchids. The sum of £104 10s. is offered for Pelargoniums in various classes; £62 for Roses in pots, £61 for cut Roses, £8 10s. for Pansies and Violas, special prizes for double and single Pyrethrums, and for a collection of ten varieties of fruit prizes respectively of £10, £8, £5, £3, and £2 are offered; and £31 10s. for other fruits. Stove and greenhouse plants, groups, and a host of other things have also liberal sums of money allotted, the aggregate amount of the schedule exceeding £600.

THE CONSERVATORY AT SOUTH KENSINGTON.—It is reported that this structure will shortly be demolished, to make room for a further extension of the School of Music.

CLASSIFICATION OF ORCHIDS.—Prof. PRYTZER'S recently published scheme of classification is based, not only on the floral structure, but also on the mode of growth of the stem, and the manner in which the leaf is rolled up. Thus, first of all, the *Cyprripedium* are cut off by their two lateral anthers. Other Orchids are all monandrous, that is, have one anther only. Of these, the first division, *Basitonae*, is composed of the *Ophrydineae* only, in them the filament is continuous with the anther, and the pollen masses bear caudicles at the end. The second great division (*Acrotoneae*) includes those Orchids in which the filament is marked off from the anther. This great group is divided, first of all, into those in which the inflorescence is in the form of a sympode, and next into

those in which the inflorescence is borne on the sides of a leafy stem or a creeping rootstock. These two groups are further subdivided according as the leaf is rolled up in the young state (convolute), or folded (duplicate). Further subdivisions depend upon the circumstance whether the blade of the leaf separates from the sheath or whether it does not, the nature of the pollen, the presence or absence of pseudobulbs, &c. Those who are not botanists may be glad to be reminded that in a monopodial stem the leaves are formed season after season at the end of the same stem, while in a sympodial growth the one season's growth bears a leaf or leaves at the end, but no further development takes place from that end, but only from the side beneath that end; the "laterals," however, generally turn upwards, so as to assume the same line of direction as the original stem. This kind of stem, therefore, may look continuous and unbroken, when in reality it is made up of a succession of "laterals" arranged one over the other to form a "sympode."

SLOW-WORMS IN ORCHID HOUSES.—Dr. PATERSON writes as follows:—"The Brittle Snake (*Anguis fragilis*, L.) or slow-worm, a native of Britain, common in England, not so common in Scotland; when full grown is about 12 or 13 inches long, generally of a dark glossy colour, moves slowly, and has a beautiful snake-like head with keen piercing eyes, and is perfectly harmless and can be made a pet. I find this snake a grand assistant to the green tree frog in the Orchid-house, as his principal food is snails. All Orchid growers hate snails, as they destroy flower-spikes and young bulbs. Some years ago a friend of mine purchased a rare *Phalenopsis* for 10 guineas; next morning, when he went to look at the rare plant, he found to his disgust that a snail had made his breakfast off the plant—a most expensive breakfast many will say. I would advise Orchid growers to give the slow-worm a trial, they can be purchased from any dealer in wild animals."

PASTURE LAND.—Mr. MARTIN J. SUTTON has recently published a detailed account of the experiments made by him in co-operation with Dr. AUGUSTUS VOELCKER on the effect of various manures on temporary and permanent pastures. The pamphlet is published at a low cost by Messrs. HAMILTON, ANAMS & Co., and is worth the serious attention of all concerned in the management of pasture-land. The experiments are conducted on a similar plan to those at Rothamsted; but whereas the experiments made under the auspices of Sir JOHN LAWES for the last twenty-five years or so have been made with a view of determining certain abstract questions in chemistry and physiology, they have often been made under conditions which would not arise in ordinary agricultural practice. Mr. SUTTON'S experiments apply especially to the effect of artificial manures in such quantities and under such conditions as might reasonably commend themselves to the grass-land farmer. The plots do not all form part of one field as at Rothamsted, where the conditions of soil, exposure, and natural vegetation are fairly uniform throughout, but occupy six different positions in which the conditions are also different, one being old pasture, another has been laid down for five-years, two others have been sown since 1884—the one with, the other without perennial Rye-grass; while the two remaining experiments have been made upon plots representing a three years' ley, with, and without Rye-grass. The manures employed consist of nitrogenous manures, such as ammonia sulphate, or soda-nitrate, superphosphate, farmyard manure, cotton cake, guano, coprolites, bone-meal, &c., each substance being used either alone or in various combinations. It is too early to arrive at definite conclusions from experiments where so much depends upon the varying amounts of light, heat, and rainfall in various seasons, but it is interesting to note that the Rothamsted experiments are confirmed in many respects, as in the effect of nitrogenous manures, in benefiting grasses and discouraging the Clovers, while potash manures do the reverse. We do not find any notes concerning the degree and date of ripeness of

the crop under varying conditions of manuring, but doubtless these will follow in due time. Decorticated cotton-cake is proved to be a valuable manure, and the value of Rye-grass is insisted on. An incidental point of great practical value comes out in the circumstance that sheep do serious injury to young pastures by destroying the Clover. It is possible that the trampling of the sheep does as much injury as the destruction of the foliage. The cost of the manures per acre varied from 14s. to £1 1s. 3d., with a nett gain on hay per acre of from 11s. 9d. in the case of plot 3 (nitrate of soda) to £1 8s. 3d. in plot 4 (superphosphate and kainit). We cite these figures merely by way of illustration, and to call the attention of our readers to a series of experiments of great interest to those concerned in the management of grass-land. The addition of tables showing the cost per acre, the increase or decrease in value of the hay per acre, and the nett gain or loss on the hay per acre will render these tables specially useful to the farmer. There is, however, so far as we can see, no indication of the cost of the labour employed.

MR. HARTMANN.—Mr. C. HARTMANN, the botanist and horticultural collector, has, we are sorry to say, succumbed to fever contracted in New Guinea. He died, as we learn from Baron von MÜLLER, in Queensland, on his return to his home. He and Mr. G. HENNER were the first who brought together a number of native tribes, before always at war with each other, and induced them to act as carriers of the luggage of the travellers at some portions of the Owen Stanley Ranges; and thus they also paved the way for the advent of Mr. ANREE by Messrs. CUTBERTSON and SAYER. At Towns, in Queensland, Mr. C. HARTMANN had a business as a vendor of plants and seeds, and for a long series of years he was interested in obtaining specimens of native plants for the elucidation of the local flora. In former years he had a good reputation in Germany as a skilful grower of Orchids. The *Sarcophilus Hartmanni* (*S. rubricentrum*, Fitzgerald) was discovered by him, and at once named and described in his honour.

MEMORIAL TO THE ROSARIAN, FRANCOIS LACHARME.—We have received the following from Mr. G. PAUL of Chesham:—"M. LÉVÊQUE, on behalf of the committee in Paris and Lyons, organised for the purpose of raising a memorial at the grave of this noted Rose grower, has asked me to distribute some circulars inviting the co-operation of the English Rose growers. Naming the request to some members of the National Rose Society, it was suggested that it would be a graceful act if the contributions of the English growers took the form of a medallion, with an English inscription on the tomb or monument, and on conveying this suggestion to M. LÉVÊQUE he writes that they would gladly accept such a contribution, and would give the English memorial a place of honour. Either Mr. D'OMERAIN or I would be happy to receive any contributions to this fund, which I need hardly recommend, so well was LACHARME'S name known to all rosarians. Subscriptions of 5s. to 10s. would suffice for all that is necessary."

KEEP THE BORER OUT.—For twenty-five years my success in beating the Apple tree borer has been almost complete. I write of the flat-headed borer (*Chrysobothris femorat*). The eggs of the borer are deposited on the south or south-west side of the tree, and never on the opposite side, and they are laid in the places where the sun's rays fall most fairly on the tree. Now if the tree when planted is set leaning to the south-west, say 15° or more, the borers will not lay their eggs on them; nor can the sun's rays strike so fairly on the body of the tree. They must be kept in position by stakes if necessary. If set upright they almost always come to lean to the north-east, owing to the injurious effect of the above causes, which retards the growth on the south-west side. The eggs are scarcely ever laid more than 4 feet above the ground. If the tree is allowed to branch lower than that there will be places on the branches where the sun will strike, making it favourable for hatching the eggs. Therefore I think it advisable to have the trees branch at least 4 feet above ground. This has been my practice, and I find it effectual. Last summer I examined my trees for borers, and in three or four, which by neglect had been allowed to lean the wrong way, I found many. *American Paper.*

PHAIUS GRANDIFOLIUS AND RICHARDIA ÆTHIOPICA.

[SEE SUPPLEMENTARY SHEET.]

THE two examples of these plants shown in our supplemental illustration were grown at Worksp Manor Gardens by Mr. T. H. SUTTON, to whom we are indebted for the opportunity to figure them. The specimen of Orchid, *Phaius grandifolius*, is that of a plant that has been well managed for a number of years, as can be observed by the vigour of its growth and its floriferousness.

This species of *Phaius*, although wanting the brighter colouring of Dominy's hybrid *P. irroratus* ×, raised from *P. grandifolius* and *Calanthe vestita*, or that of *P. tuberculatus*, is yet a plant that has remained a favourite for a century, and is to be found in most collections of stove plants. The petals are white without, and chocolate-brown within. The oblong cucullate lip, the base of which is folded over the column, is white, with yellow stains on the throat and disc, the sides of the lip being marked with crimson both inside and out. It flowers in winter and spring, and is of easy growth.

The specimen of *Richardia æthiopica* (*Calla*) is an exceedingly good one, and would form a desirable decorative object in any collection of plants. So well known a plant needs no further remark than to caution our readers against the practice of drying-off the plant after growth is fully developed and the season of bloom over. Being a true aquatic from the Nile, this old practice could but prove injurious to growth and free flowering, as is shown by the fine examples produced under the more rational and generally adopted treatment of the present day.

NURSERY NOTES.

ORCHIDS AT MESSRS. F. SANDER & CO.'S

ON the north side of Messrs. Sander & Co.'s establishment at St. Albans a fine new Cattleya-house 300 feet long, 26 feet wide and 14 feet high is now to be seen, and as in it some new and useful ideas are worked out, its interior arrangements may be noted with advantage. The roof consists of a number of spans of low pitch running transversely, thereby obtaining the greatest possible amount of light. Each span is supported by a light iron pillar, and for the rest of the needful strengthening and support to hold the large building secure neat ornamental corner pieces and brackets of iron are used, the whole of the iron-work being supplied by Messrs. Measures, Bros., & Co., Southwark Street, S.E., and thus the entire interior is unobstructed by the girders and tie-rods generally employed; but in order to further strengthen the building, eleven rows of 1-inch gas-piping are fixed to the woodwork of the roof over the side staging and walks, and these, while giving great strength to the building, afford means for hanging blocks and baskets. The side staging is of light angle-iron, placed at the proper distances to take ordinary red roofing tiles, thus forming an ideal staging—clean, moist, durable, and affording little or no harbour for insects. Fourteen rows of hot-water piping supply the necessary heat, and the centre bed of brickwork forms a pit in which freshly gathered fallen leaves are placed to maintain a healthy atmosphere in the house. Over the bed is placed the necessary open staging, rising in steps to the middle, and in connection with it a valuable innovation must be noted. The ordinary staging, constructed entirely of wood, is sooner or later sure to decay and cause mischief, but a staging of iron is cold, and generally disliked by plants; the idea, therefore, occurred to Mr. Sander that the framework or superstructure of the middle staging should be built with the house, and at each pillar supporting the roof, an arch (one brick thick) in brick and cement is thrown across the bed from wall to wall, the iron pillar forming the key in the centre. The upper surface of these arches rises in steps of the necessary gradation, and all that is required is to place on the usual wooden shelves at the proper distance apart,

The new Cattleya-house at St. Albans will give many valuable ideas to intending builders or renovators of old houses.

It is possible to note only the main things in flower in such a vast establishment, let us therefore proceed at once to some of the pretty and natural rockeries with which many of the principal houses are furnished, and about which the principal plants in bloom are suspended, to help out those planted on the rockeries in making an effective display. In the Lælia-house a splendid show is made by the many new white varieties of *Lælia anceps*, of which *L. a. Sanderiana* and *L. a. Stella* are the best; one fine specimen of the latter had several spikes of four to five flowers each; *L. a. Schroderæ* is a charming thing, with delicately pink-tinted petals, with crimson feather on the tips; and *L. a. Veitchiana*, a very distinct variety, with white segments, and decidedly blue-tinted labellum. On or over the same rockery among foliage and twining plants are some fine examples of *Lælia autumnalis atro-rubens*, *L. albidæ*, *L. elegans*, and many other species.

In the large established Cattleya-house the same pleasing arrangement of flowers is found: there are many and varied forms of *Cattleya Trianae* with gorgeous flowers, the show of them also extending far into the house. Some selected forms of *C. Percivaliana* are also in bloom, and several fine plants of the best forms of pure white *Lycaste Skinneri*, a plant in which, perhaps, no one has yet found a fault. The next large intermediate-house has a similarly arranged display made up of the many fine fresh imported varieties of *Cypripedium insigne*, some having almost black markings, and one with flowers intermediate between that known as *syhetense* and the purple-spotted *C. i. violaceo-punctatum*; some fine sprays of *Oncidium tigrinum*, *O. pratextum*, *O. chrophorum*, *O. Phalenopsis*, several good *Calanthe veratrifolia*, *Zygopetalum Burkei*, *O. varicosum cruentum*, equal to the best *varicosum* in size and form but with a blood-red base to the lip; several fine *Masdevallia tovarensis*, and plants of the lovely little *Ornithocephalus grandiflorus*, which has white flowers of very curious form.

Angraecum make a fine sight just now in their house, and no one who saw the scores of sprays of pure white flowers on the plants of the new *A. Sanderianum* could fail to pronounce it an acquisition of the highest merit. In size and form of its flowers it surpasses the fine old, but now rare, *A. bilobum*, and is, moreover, a weed to grow, to which indictment the old species cannot plead guilty. *A. sesquipedale* also has many flowers, *A. Scottianum* a few; *A. bilobum*, and *A. Leonis* are in flower; so also the new *Acranthus Grandidierianus* (Rehb. f., *Gardeners' Chronicle*, January 21, p. 72), and the new *A. Kimballianus* and *A. Germinyanus* are showing for flower. Among the *Dendrobiums* are a fine show of imported *D. nobile* showing great variation in form, colour and odour; one has rightly been selected for naming, and has been called *D. nobile vernixium*; its colour is the same as the fine *D. n. nobiliss*, and the whole of the segments on both back and front are shining as if varnished, which certainly adds to the beauty of what would even without it be a sufficiently fine and distinct flower. Also in bloom are *D. Ainsworthii roseum*, the new *D. Friedericksianum* (*Gardeners' Chronicle*, November 26, 1887), *D. bigibbum*, *D. superbiens*, *Epidendrum Endresi*, and other *Epidendrum* and *Dendrobium*; and in one group a fine lot of all the varieties of *Coleogyne cristata*.

The *Odontoglossums*, which have often been noted, fill several large and long houses, and as the question of the proper time to repot these plants is assigned by some to the summer, it will be well to note that here the repotting of the thousands of *Odontoglossums* is commenced with the new year, and is just now in active progress; Mr. Sander is convinced that this is the proper time to repot cool-house Orchids, and the condition of his stock bears out his practice. Among the many fine *O. crispum* and *O. Pescatorei* in bloom are the rare and pretty *O. Schillerianum*, *O. Mirandum*, *O. pardinum*, *O. Plumeanum violaceum*, *O. Harryanum*, *O. odora-*

tum albidum—the form which Lindley named *O. navium majus*—*O. Lindleyanum speciosum*; an unique plant, and a really ornate *Odontoglossum*; *O. bictoniense album*, and (not in flower) a little lot of the extremely rare and difficult to import *O. Warscewiczii*, which thrives best in a temperature a little cooler than does *Miltonia vexillaria*.

On the site of the old nursery in the town, taking the place of the old houses, there have been built a number of neat span-houses connected by a corridor. This establishment is much devoted to crossing and raising Orchids from seeds, and in several of the houses countless little hybrids appear, *Masdevallia Gelenium* ×, Mr. Sander's first cross with *M. Shuttleworthii*, being in bloom.

In the *Cypripedium*-house there were in bloom the handsome *C. Io* ×, *C. plumerum* ×, *C. conchiferum* ×, *C. cardinale* ×, *C. vexillarium* ×, *C. Artburianum* ×, *C. grande* ×, *C. Harrisianum venustum* ×, *C. ænanthum superbum* ×, *C. Dayanum*, *C. Curtisii*, &c.; and in a house to themselves, planted out, are a large quantity of *C. caudatum* sending up scores of flower-spikes. The collections of *Phalenopsis* and *Masdevallias* are also in this nursery, and here, in a tolerably cool house of even temperature, the *Bolleas*, *Batemannias*, and *Pescatoreas*, which so many fail to grow, seem to luxuriate. In one of the cool houses will be found a splendid lot of *Oncidium macranthum* and the rare *O. undulatum* and many other scarce plants. *J. O'Brien*.

LAW NOTES.

MRS. REYNOLDS v. MESSRS. JACOB WRENCH AND SONS.

A CASE of considerable importance to seedsmen and growers came before Mr. Justice Denman in the High Court of Justice on Monday last. The action was brought by a Mrs. Reynolds, a seed grower in Huntingdonshire against Messrs. Jacob Wrench & Sons, seedsmen of London, to recover £350. This amount was admitted by the defendants, but they raised a counterclaim for damages under the following circumstances:—In 1884 they sent to the plaintiff some stock seed of Yellow Tankard Turnip and in due course received what they thought was the produce, amounting to about 60 bushels. This was sold in November, 1885 to Peter Lawson & Sons, Limited, of Edinburgh, as Yellow Tankard Turnip seed, and as such sold by them to various customers. It was afterwards discovered that the seed was Purple Mammoth Turnip, and claims were made by P. Lawson & Sons' customers against them, amounting to nearly £100, which they in turn claimed against Messrs. Jacob Wrench & Sons, who claimed the amount from Mrs. Reynolds by way of damages for the breach of contract to grow the stock seed sent her. The action came on for trial at the Huntingdon Assizes, when the jury found in the defendants' favour on the question whether Mrs. Reynolds had returned the wrong crop, and the case was adjourned to London on the question whether the defendants could claim from the plaintiff the amount for which they are liable to Peter Lawson & Son, Limited, or whether they were entitled to nominal damages. It appeared that the defendants' custom was to print on their invoices the following guarantee clause:—"Messrs. Jacob Wrench & Sons give no warranty, express or implied, as to description, quality, productiveness, or any other matter connected with the seeds they send out, and they will not be in any way responsible for the crop. If the purchaser does not accept the goods on these terms they are to be at once returned." This clause was on the invoice which accompanied the stock seed when sent to the plaintiff to grow, and was also on the invoice which was sent by the defendants to Peter Lawson & Sons, Limited. The contention on the part of the defendants was that, notwithstanding that clause, they were liable to Peter Lawson & Sons, Limited, as at the time the seeds were sold to them it was understood that they were selling Yellow

Tankard Turnip seed and no other, whereas the seed sold was Purple Mammoth Turnip, and evidence was adduced to prove a custom in the trade to the effect that when the words "seeds of sellers' own growth and stock" were used, it meant that the seed in question was grown from seed specially selected by the seed merchant, and consequently the non-guarantee clause did not apply, and that in the event of any other seed being supplied the seed merchant would be liable to all the consequences. But apart from this it was contended that the words in the non-guarantee clause could not be applied in this case, as the word "description" referred to the goods sold, which were Yellow Tankard Turnips, and not the Purple Mammoth Turnip, which was delivered.

On the part of the plaintiff, the alleged custom was repudiated, and her counsel relied on the non-guarantee clause used by the defendant, as showing that it was part of the terms on which the seed was sold, and that there was no liability on their part. He also contended that the question turned on the construction of the contract between the plaintiff and the defendant, and no damages could be given which were not in the contemplation of both parties to the contract at the time it was made. By the defendants inserting the non-guarantee clause on the invoice accompanying the stock seed sent to the plaintiff they had given her notice that they did not hold themselves liable to their customers, and consequently such damages could not be contemplated by her in the event of a breach of contract to grow the seed, and she could not know that any arrangement had been made when the seed was sold, which was inconsistent with the non-guarantee clause.

In the result the judge held that the defendants had failed to prove the alleged custom in the trade, and that the defendants must be held to their non-guarantee clause; and that there being no liability on their part they could only claim nominal damages against the plaintiff for the breach of her contract, which he assessed at one shilling. He gave judgment for the plaintiff for the amount claimed less the one shilling, with costs of action.

TREES AND SHRUBS.

ORNAMENTAL BERRY-BEARING SHRUBS.

(Continued from p. 19.)

Gaultheria procumbens must on no account be omitted from our list of hardy berry-bearing shrubs, for it is well worth looking after. The fruits are scarlet and edible, and the plant is highly ornamental with its white, pendulous, axillary flowers.

G. shallon has purple berries and white, rather inconspicuous flowers. It is of taller growth than the latter, under good cultivation attaining to a height of fully a yard.

The Common Privet (*Ligustrum vulgare*) is well worthy of attention on account of the great wealth of ebony-like berries it produces. A few twigs with the accompanying fruit arranged with the berried Holly is very effective, and even when intermixed with cut flowers in a vase the rich dark berries show well out against almost any colour of flower.

Bouthanmia fragifera, although somewhat tender, is really a first-class evergreen shrub for winter decorative purposes. The large Strawberry-like fruit is very ornamental and imparts quite a feature to the shrub for several months. We have noticed this Nepalese plant thriving well in sea-coast gardens in Wales, but inland it cannot be relied upon, hard frosts telling hard upon it.

Lucuba japonica is another excellent plant from which to cull a few berried twigs for the garnishment of the Christmas table. To have the berries in abundance either fertilisation must be resorted to artificially, or the male and female plants grown side by side, or at least, at a reasonable distance apart. The berries are large and, like the leaves, of good

substance lasting for a considerable length of time either in or out of water.

Shepherdia canadensis and *S. argentea* are highly ornamental shrubs with distinctly silvered leaves and an abundance of edible scarlet fruit. It is hardly correct to say that both species of *Shepherdia* have scarlet fruit, for those of *canadensis* are orange-red, while those of the latter, which is popularly known as the Buffalo-berry, are bright scarlet. This genus of plants is far too little grown when we take into consideration the beauty of both foliage and fruit.

Cotoneasters of sorts are highly ornamental plants during the winter months from the great abundance of conspicuous fruit which most of the species produce.

C. Simonsii is one of the best when considered in an ornamental aspect, for the large oblong vermilion coloured berries are produced in great abundance, and are remarkably persistent in character.

C. vulgaris has spherical shining black, yellow, or scarlet fruit, and is of interest as being the only native species. We have cultivated it from plants derived from its native habitat—the Orme's Head—and where it grows amongst calcareous rocks exposed fully to the scorching sun, and in company with two other rare natives—*Pyrus aria*, and that sweet little Orchid, *Epipactis ovalis*.

C. frigida, with its large clusters of conspicuous scarlet berries is well worthy of attention, and is quite a feature of the grounds in which it is cultivated.

C. microphylla, *C. buxifolia*, *C. thyrsifolia*, *C. Wheeleri*, and several others, are likewise highly ornamental fruit-bearing plants, and being of free growth are commonly enough to be found in our collection of trees and shrubs.

Crataegus pyracantha, or the Evergreen Thorn as it is usually styled, bears large clusters of orange-scarlet berries, which remain intact during the greater part of the winter, unless they are removed by birds. *A. D. Webster.*

(To be continued.)

JUNCTIONS OF PATHS AND ROADS IN THE GARDEN.

The series of small figures at fig. 20 explain themselves, they being diagrams of good and bad examples of junctions, the bad being the two rectangular ones. Paths are much better looking when carried out with gentle curves, around the central plot of turf, or a shrub, or group of plants. Right angles in walks in common use are in bad taste, because erring against common sense, for we know how futile it is for the gardener to keep that obtrusive right angle in good order for any length of time. The rectangular junction can be employed when a gate opens into the lane beyond the boundary, or when a temple, summer-house, or other garden adjunct of an ornamental character stands at the point of junction.

The examples of serpentine and simple curves are in true taste, and are made pleasanter by the masking groups, large and small, of shrubs, and, if needs be, trees at their margin. To our English ideas the shrubs come a little too close to the path in some instances; but in sunnier France, whence these illustrations came, people are glad of the shade of the neighbouring groups, and would not think our wide foregrounds and expanses of free turf afforded any advantages.

FOREIGN CORRESPONDENCE.

OVERVEEN BULB SHOW.

JANUARY 13-16.—We learn that the show of flowering Hyacinths and Tulips, which was held at Overveen from January 13-16, was most successful, though the competition was not considerable, there being only two exhibitions of Hyacinths in pots, three for Hyacinths in water, and one for Tulips.

In the class for thirty-six Hyacinths in pots, Mr. P. W. Voet showed a very fine and well-grown collection, for which the 1st prize (Gold Medal) was awarded. This collection consisted chiefly of such

Grand Lilas, D.W. La Tour d'Auvergne, D.B. Charles Dickens, D.R. Prince of Orange.

In the class for eighteen Hyacinths in pots, the 1st prize was taken by Mr. Bos; in the class for twelve Hyacinths in pots, 1st prize went to the same; 2nd to Mr. P. W. Voet.

In the three classes, twenty-four, eighteen, and twelve Hyacinths, in water, all the 1st prizes were taken by Messrs. Peter van Velsen & Sons, who showed perfect and large flowers of S.W. La Grandesse, S.W. Mont Blanc, S.W. Madame van der Hoop, S.W. British Queen, S.R. Lord Macaulay, S.R. Incomparable, S.R. Charles Dickens, S.B. General Havelock, S.B. Argus, S.B. Climax, S. violet Haydn, S. yellow Ida, D.R. Dagmar, D.B. Charles Dickens, D. W. Prince of Waterloo. Second prizes were taken by Mr. W. Blom and Mr. L. Roozen, Bz.

Tulips.—Mr. T. W. Voet showed two collections of eighteen pots, for one of which, the 1st prize was awarded, and consisted chiefly of well known sorts, as Joost van Vondel, Proserpine, Pottebakker, Le Matelas, Canary Bird, Tournesol, La Parfaite (Keizerskroon, double).

Mr. E. Krayff showed a new single red Hyacinth; it has a very large compact spike of most distinct colour, and should be a useful addition to the dark red early Hyacinths. *Correspondent.*

FASCIATED PETUNIA.

A good instance of fasciation is represented at fig. 21, which illustrates an abnormal growth of a Petunia, engraved from a photograph kindly forwarded to us from Brisbane by Mr. W. Soutter of the Acclimatisation Society of Queensland, who states that there were thirty-four expanded flowers on the stem, and forty-three unexpanded. Fasciation, which consists of the production and development of an abnormal number of buds, which in growing into shoots do not separate one from another, but remain fused in one mass, is exceedingly common in all fast-growing plants.

USEFUL INVENTIONS.

MESSRS. CORY, SOPPER, FOWLER & Co. have introduced a substitute for fumigating with tobacco-paper, in the shape of a hollow cone of charcoal containing a bottle of some liquid. The charcoal is set on fire, the bottle bursts, and a vapour is set free, which, it is alleged, is fatal to insects, but not injurious to plants. Should it bear out the expectations raised, it will indeed be a boon to gardeners. So far we can report favourably on its effects as regards greenfly, and we shall report more fully when our experience permits us to do so.

AMERICAN NOTES.

ORCHID JOTTINGS IN AND AROUND NEW YORK.

THE first collection I saw, during my recent visit to the States, was that of W. H. de Forest, Esq., of Summit, New Jersey, where there was at the time of my visit a good display of *Cattleya Trianae*, including some very fine varieties; one of them was the true *C. Trianae alba*, and another was quite a novel form, in which the sepals and petals were straw-coloured, and rosy-pink *Cattleyas* and *Laelias* are special favourites of Mr. de Forest, and of which he possesses a large number. The majority of them had made fine strong growths and flower-sheaths. Quite a rich display of blossom was made by the *Cypripediums*, *Phalenopsis*, *Oncidium*, *Odontoglossums*, and other species; the condition of the plants doing much credit to Mr. W. Vollmer, who has the special charge of the collection. The entrance to the Orchid-houses was through a kind of rockery, filled with Ferns, Palms, &c., and having a winding path in the centre. The Orchids when in bloom are placed in this house, where they are seen to advan-

FIG. 20.—FORMS OF PATHS.

excellent sorts as S.R. Garibaldi, S.R. Général Pelissier, S.R. von Schiller, S.R. Cardinal Rampola (new), S.W. L'Innocence, S.W. Baron van Thuyll, S.B. Sir Henry Barkley, S.B. Charles Dickens, S.B.

tage, and have a very handsome effect. It may be stated that about 500 blossoms of *Cattleya Trianae* were cut from this collection before Christmas.

One of the enthusiastic amateurs of New Jersey, and who has a charming place, is James R. Pitcher, Esq., of Shorthills, President of the New Jersey Horticultural Society. In his estimation there is at the present time no species of Orchids to compare to the insinuating *Cypripedia*, of which he has a wonderfully rich collection; but the day is not far distant when all good Orchids will find a home in his houses, which are well adapted to the growing of these plants. The gardener, Mr. R. Brett, is an energetic and painstaking cultivator, very fond of the plants entrusted to his care. Many *Cypripediums* were in flower, and some very fine *Oncidium*s, *Aërides*, *Phalaenopsis*, &c., interspersed with *Nepenthes* and other foliage plants, of which there is a rich collection. On the day of my visit there were present

great size, beautifully grown, and almost priceless value. A handsome new house has lately been erected for the accommodation of the rich collection of *Cattleyas* and *Lælias*, and another adjoining for *Odontoglossums* and *Masdevallias*, both of them being admirably adapted to the requirements of these plants. Mr. Wm. Robinson, a well-known excellent gardener and cultivator of Orchids, has superintended this place for a number of years, and has laboured assiduously to bring it to its present state of perfection. It would be impossible to name here, in detail, all the fine Orchids I saw here. Some of the *Cattleyas* and *Lælias* are really of gigantic proportions, one plant of *L. anceps Sanderiana* having twelve finely developed flower-spikes. The *Odontoglossums* are as superb as the former, and as well grown as they are in England, which redounds to the credit of the cultivator, seeing that in America he has to contend with the great heat that prevails

one side by a large lake, the surrounding scenery being enchanting. It is unlike other places in America, inasmuch as it has the appearance of age about it, and more resembles what we find in old countries. A general collection of plants is grown here under the direction of Mr. Harris, who has had charge of the place for a great number of years. Everything bears evidence of skill both in and out-of-doors. Some handsome *Cypripediums*, *Cattleyas*, *Odontoglossums*, &c., were in bloom, as was a fine batch of *Calanthes*, some of the spikes bearing as many as forty flowers.

My next call was on De Witt S. Smith, Esq., of Lee, Massachusetts, where a pleasant surprise was in store for me. The morning was intensely frosty, with deep snow, but I found his houses ablaze with Orchid bloom, rich in quality and abundant in variety. The flowers of *Lælia anceps* were the largest I have ever seen; *Cattleya Percivaliana*, *Vanda Sanderiana*, *Oncidium varicosum errentum*, *Odontoglossum crispum* in variety, were also very fine: to these may be added hundreds of *Cypripediums*, many of the *C. Spicerianum* having two flowers on a scape. Mr. Smith obtains more blossom from a given number of plants than is probably done elsewhere, which is doubtless accounted for by the extraordinary vigour of his plants, and the abundance of their strong roots. Mr. E. Norman, the gardener, has brought this collection into fine condition; the specimens of *Cypripedium niveum* were the best grown that I saw while in the States.

It was a matter of course that I visited the garden of Erastus Corning, Esq., of Albany, New York, who has one of the oldest established and most complete collections in America. The show of *Cattleya Trianae* here was far finer in variety and greater in number than in any other establishment that I visited. All the *Lælias* and *Cattleyas* were in superb condition, the leaves thick and leathery, and the long aerial roots in great abundance. The rare and distinct *Lælia Crawshayana* was in bloom, as was the new *L. Gouldiana*; both of them are apparently natural hybrids between *L. anceps* and *L. autumnalis*. *L. Gouldiana* is the finer of the two, and at the same time it is a really good and free winter blooming Orchid. The species of *Phalaenopsis* are Mr. Corning's favourites, and of which he has probably the most complete collection in cultivation, all of which are doing well. *Cypripediums* in America are especially good, but here were some of the finest, such as *C. Harrisianum superbum*, *C. Arthurianum*, *C. vexillarium*, *C. Morganii*, all of which were in flower at the time of my visit, and in larger specimens than any I have seen elsewhere. The collection of *Odontoglossum* is also a very rich one, the plants being in excellent condition; in fact, the collection does great credit to Mr. William Gray, the gardener in charge, and who is ably assisted in the cultivation by Mr. Goulding, a well-known Orchid grower and writer, contributing to both English and American periodicals.

My next move was to Utica, to the horticultural establishment of Mr. Wm. Mathews, who has formed a large and well-grown collection of Orchids. He is a man who evidently understands the requirements of these plants. Most of the houses are sunk in the ground with simple wooden stages; as much of the virgin soil as possible is left inside the house, paths being dug where wanted. This plan insures natural humidity, and minimises the expense of frequent damping, while the growing conditions are secured. It would be difficult to find better cultivated *Cattleyas*, *Lælias*, *Odontoglossums*, *Cypripediums*, *Phalaenopsis*, in fact anything seems to grow freely and sturdily. The show of bloom of the genera named was grand for the time of year, and included many fine varieties, all of which are cut for the New York market. Orchids are but a branch of this business; Carnations, Roses, Poinsettias, foliage and ornamental plants generally being grown in large quantities.

W. S. Kimball, Esq., of Rochester, owner of what I may call the "Peerless" collection, received my next call. His is, as far as I know, the most complete collection in America. Mr. Kimball is an

FIG. 21.—FAS TATED PETUNIA. (SEE P. 116.)

about forty representative horticultural men of New Jersey—gardeners and nurserymen—who, at the invitation of Mr. Pitcher sat down to an enjoyable luncheon; and, if I may judge from the speeches that were made, Mr. Pitcher has reason to be proud of the estimation in which he is held by them.

Among the trade collections Messrs. Siebrecht & Wadley, of New Rochelle, New York, claims special attention; large numbers of *Cattleyas*, *Lælias*, *Odontoglossums*, and *Oncidium*s being grown, the business done in these plants being extensive, especially in all winter-blooming Orchids, the demand for them at present being greater than the supply. At the time of my visit an enormous number of plants of *Lælias* were in bloom; these were associated with almost equally numerous *Cattleya Trianae* and *C. Percivaliana*. Mr. Rose, a young beginner, is in charge of the collection, and handles the plants well.

My next visit was to the noted collection of F. L. Ames, Esq., of North Easton, where are to be seen the gems of the most showy species, the plants of

during the summer months. Mr. Robinson is a thorough worker, and has done a great deal to spread a taste for growing Orchids by manfully combatting every difficulty until success has crowned his efforts. Much good is also done by such amateurs as R. Frohock, Esq., of Malden, Massachusetts, who well cultivates a small collection without the assistance of a gardener, and yet his plants will bear favourable comparison with any that I have seen for cleanliness and vigour. A splendid variety of *Vanda Sanderiana*, a novel form of *Cypripedium Spicerianum*, *Odontoglossums*, *Oncidium*s, *Coclogyne barbata*, &c., were in flower. At the time these notes were made, the overlapping portion of the pouch in Mr. Fröhock's *C. Spicerianum* was of a slaty-blue colour, and, so far as I know, the variety is remarkable and rare.

A general opinion prevails in America that the residence of H. H. Hannewell, Esq., of Wellesley, Massachusetts, is one of the most beautiful in the States. The grounds are planted with coniferous and other trees of great beauty, and are bounded on

amateur in the truest sense of the word; caring for the tiniest beauties as much as for the most gorgeous representatives of the order. He has done more to popularise Orchids in America than any other man, by growing a collection to which the public have free admission, and by continually publishing lists of his Orchids. In flower were grand specimens of Vandas, Angraecums, Aërides and Saccolabiums, magnificent Cattleyas, Phalaenopsis, Epidendrums and Schomburgkias, Laëlias, &c., down to the minutest of Masdevallias, Pleurothallis, Megacalinium, &c. Masdevallia muscosa being most charming. A great number of Cyrtopodiums were in bloom, including Kimball's variety of *C. purpuratum*, the finest form of this species, twice the size of the ordinary one; a new and magnificent Schomburgkia in the way of *S. tibicinis rosea*, and the new *Laëlia anceps Sanderiana*, with two spikes, one bearing four blooms the other five, all of large size. The new *Laëlia Gouldiana*, named in compliment to Jay Gould, the "American Railway King," is also to be seen. But I have not sufficient space to enumerate all the plants in bloom; one cannot do justice to such a grand collection in a short notice. The condition of the plants leaves nothing to be desired, and Mr. George Savage deserves all credit for his management of the plants.

The accompanying photograph [which we hope to reproduce shortly. Ed.] comes from Fred. Scholes, Esq., of Brooklyn, who, in Phalaenopsis culture, is the Partington of America. Mr. Scholes supplies his plants with liquid cow manure when they are in active growth—with marvellous results; on one plant I counted 14 leaves from 8 to 15 inches long, of good substance, and 3 large branching flower-spikes. These plants Mr. Scholes assured me were quite small three years ago. Mr. Gardiner, who has charge of this collection, propagates the plants by cutting up the old flower-stems, and inserting them in sand. There was a large number of Orchids in blossom here, including some fine varieties of Cattleya Percivaliana, all being in a clean healthy condition, and grown mostly in pure Sphagnum.

I saw, also, a fine lot of Orchids at Mr. John S. Bush's establishment, Tremont, one of the oldest collections in the State of New York; there were many fine species and varieties, Odontoglossums and Cattleyas being specially well done. Any one visiting New York and interested in horticulture should visit some of the magnificent Rose-growing establishments, notably those of Mr. May, of The Summit, New Jersey, and of Mr. Wood, of Natick, New York. *Joseph Godseff.*

HOME CORRESPONDENCE.

THE ROYAL HORTICULTURAL SOCIETY.—At the present critical juncture of the Society's affairs, every suggestion will, I feel sure, receive consideration from those who are endeavouring to reconstitute it. It has occurred to me that the sympathy and support of practical gardeners could be enlisted on behalf of the Society if some inducement were held out to them to take an interest in its proceedings. Now this, I think, may be done if it were decided to confer upon a limited number of the leading gardeners throughout the country the honour of Associate of the Royal Horticultural Society. This would cost the Society nothing, and might eventually bring much profit. It is well known that among the several thousands of gardeners whose names occur in the garden Directories there are men of various degrees of ability, and I think it would be to the advantage of horticulture if there were some authoritative body, such as the Royal Horticultural Society is, or should be, having the power of conferring some such distinction as suggested upon the best of these gardeners. The honour of such a distinction would, I feel sure, be much appreciated, and the Society would be a gainer. Suppose that from among the 6000 or 7000 gardeners the Directories tell us there are in the country 500 of them were selected as Associates, it would, I think, excite the interest and draw the support of an influential class of practical horticulturists—the backbone, in fact, of horticulture in the country, who by their position

and influence would be able to help the Society in many ways. If selected from every part of the country a knowledge of the doings of the Society would be disseminated. The Associates would, in fact, be in a sense the provincial representatives of the Society. The honour of an Associateship of the Royal Horticultural Society, if conferred only upon those gardeners who had attained to a considerable degree of eminence in their profession, would, I believe, be highly appreciated by the recipients, and coveted by those who aspire to become masters of their art. An Associateship would be looked upon as a certificate of ability—would, in fact, be equivalent to the best of testimonials, and would prove of real value to a man under various circumstances in which the best of gardeners are sometimes placed. All Associates should have the privilege of a free pass to the Society's gardens, to its committee meetings, and also to its exhibitions up to a certain time in the morning of the shows; but he should have no vote in the management of the Society unless he became a member, and this I think he should be allowed to do by payment of half-a-guinea yearly; he should then enjoy all the privileges of a one-guinea membership, which I consider ought to include a voice by vote in the management of the Society's affairs. An Associate paying half-a-guinea yearly might be styled an Associate Member, there would then be Fellows who pay two guineas or more, members who pay one guinea, Associate Members who pay half-a-guinea, and Associates who pay nothing. Such are my suggestions, which I venture to think, if carefully carried out, would result in the interests of the Society, and the advancement of horticulture. *J. Woodbridge.*

—Is Mr. Burbidge becoming Hibernianised that he should have adopted such an unhappy metaphorical object as the *Great Eastern* in likening the Society to that doomed and useless vessel? It seems suddenly to have dawned upon the writer that he had made a mistake, and striven to show that, if the *Great Eastern* is to be destroyed, her material is to be utilised in some other fashion. Here again he is in unhappy form, because the friends of the Royal Horticultural Society have no desire to see its component parts broken up for reconstruction. Once disintegration is accomplished, "not all the king's horses and all the king's men" will be able to put the Society together again. The "old ship" may be all the better for fresh manning, but the want just now seems to be some deep water into which she can freely float. It will take a lot of gushing sympathy to furnish that desideratum. It seems to be a time when a little practical help is worth a lot of sympathy. Amongst officials it is so natural a belief should exist that only more of the same article is needed to regenerate this society in particular as well as societies in general. I am rather disposed to think that the Royal Horticultural Society has been rather too much "officialised" already, and that a little less restraint would do it a lot of good. *Spadr.*

CULTIVATION OF AMARYLLIS.—The remarks I wrote on Mr. Douglas' treatment of the Amaryllis have brought from him, no doubt, what he really meant to say at p. 56, and a long article very interesting to many of your readers. I have no old books in which to hunt up an article on the Amaryllis, but I have grown the older varieties for nearly forty years, and have found them to throw up flowering stems more freely than some of the stronger kinds (new?). The points I took exception to in Mr. Douglas' letter were that he recommended a 3-inch pot to grow the bulbs in, without any reservation; the other was the shaking out and re-potting. In my opinion the plants want no shaking out, but should be rested without any loss of the roots; that is my reason for advocating the potting of the bulbs soon after flowering, and by so doing, and growing on, the pot becomes full of roots, and the plants very strong in consequence. The resting should take place, then, in a gradual manner, with full exposure to sunlight, and no more water given than is sufficient to keep the roots alive and healthy. With this treatment the plants start into growth with great vigour, and can be forced or retarded as may be required. I grew the older varieties largely at one time, and found them very useful as cut flowers in large vases. Unfortunately I was cleaned out of nearly all my stock—Vallotas as well—by the Eucharis mite; but I saved the Eucharis mostly by using lime-water, and now my stock is quite healthy. I think Bentley's Insecticide will be found a perfect cure for the Eucharis mite; we have also used it for the Gardenias; it destroys mealy-bug by the slightest touch, whereas all others that I have

used required to be brushed in when applied, otherwise no effect was apparent. *Wm. Culverwell, Thorpe Perrow.*

"TURNER MEMORIAL" PRIZES FOR 1888.—An idea prevails that the prize money available from this fund should be set apart to give prizes for florists' flowers only. This is an error. The expressed wishes of the committee were, that as the late Mr. Turner had a mind in active sympathy with every branch of horticultural work, and had introduced new varieties of fruit and vegetables as well as flowers, prizes should be given for fruits and vegetables. Acting on this assumption the trustees have decided to give a 1st prize of £10 at the Grand Yorkshire Gala, York, June 13 to 15, for a collection of ten distinct varieties of fruit. The Society will give £5, £3, and £2, as 2nd, 3rd, and 4th prizes. At the Crystal Palace, on October 11 to 13, the following prizes for twelve dishes of vegetables, distinct—1st prize, £4; 2nd, £3; 3rd, £2; 4th, £1. These prizes are open to gentlemen's gardeners only. *Jas. Douglas, Hon. Sec. to the "Turner Memorial" Fund.*

VERONICA LYCOPODIODES.—My recent article in these columns (see p. 20) upon *Veronica cupressoides* affords an excellent example of the easy manner in which one may sometimes jump at a wrong conclusion. A few days after its publication I received from Mr. R. Lindsay, of the Edinburgh Botanic Garden, a specimen of the plant of which I have represented a twig at fig. 5 r, and which I then thought was merely another variation of *V. cupressoides* var. *variabilis*. In this conjecture I was wrong, for the specimen that Mr. Lindsay has now sent—taken from the same plant as the twig represented by fig. 5 r—proves that the name under which it was cultivated (namely, *V. lycopodioides*) is correct. But the adult and normal states of the plant are very different from the condition I figured, and except for the evidence Mr. Lindsay has afforded me, would never be recognised as belonging to the same plant. Mr. Lindsay writes as follows concerning it:—"Our plant is now about 8 inches in diameter, and 6 inches in height. Until quite recently it did not answer to any description that I had seen of *V. lycopodioides*, and those who have seen the true plant in New Zealand failed to recognise our plant. At first the leaves were all long and subulate, now they have assumed a different appearance, being much shorter and more imbricated." On a future occasion I shall hope to give a figure of a branch of *V. lycopodioides*, but for the present I will content myself with saying that in its adult form the leaves are very broad and short, with a mucronate apex, closely imbricated, and arranged in four rows, so that the twigs are square with sharp angles. It may be well to explain what perhaps I did not make quite clear in the article alluded to, that I do not regard the forms given under fig. 5 as distinct varieties of *V. cupressoides* var. *variabilis*, but as merely transient conditions of growth due to some cause of which at present we have but an imperfect knowledge. They are not permanent, and so far as I have seen it is only some of the twigs on the plants that show such variation, and not the whole plant. Mr. Lindsay states that he regards these variations "as being due to feeble health in the plants producing them. Healthy plants, so far as I have seen, do not vary; but by weakening the plants—that is, by placing them in a warm house, or by striking cuttings of them in heat—they then show variations;" but I fear that this theory will scarcely apply to the Kew plants, which are quite healthy, and are growing out-of-doors, but yet produce variations, which would seem to me due, to some extent, perhaps to soil and the amount of moisture received, but I have one specimen from a dry soil, showing the same variation as I have seen on a plant grown in wet soil, and both healthy plants. Probably many factors combine to cause this variation, but to whatever it may be due it is most interesting to study, and one is tempted to speculate whether the pinnatifid-leaved variations do not give us some idea of the ancestral form or forms from which these plants have descended. It would be interesting to know if seedling plants of these species go through similar variations, and also if New Zealand botanists have observed any similar variations on these plants in a wild or cultivated state in New Zealand, I can find no evidence of anything of the kind upon the specimens preserved in the Kew Herbarium. *N. E. Brown, Kew.*

THE SCAB OF THE POTATO.—Dr. J. Brunchorst, of Bergen, has recently published his observations on the "scab" of Potatoes. This disease, known in

Norway as "skurv," and in Germany as "schorf," or "grind," so far from being due to unsuitable chemical or physical conditions of the soil, as Schacht, Sorauer, Frank and others have supposed, is caused by a parasite fungus allied to *Plasmiodiophora*, and which the discoverer proposes to call *Spongospora Solani*. Scab, as is well known, consists in the formation of pustules on the skin of the Potato, which then dry up and crack, or give access to damp; these pustules may be eaten out, and crater-like depressions left in the place. Brunchorst finds that the pustules are due to the presence of a plasmodium in the cells which are about forming the corky covering, and in consequence of its presence the development of the cells is accelerated, hypertrophy results, and the wart-like pustules are formed. The writer states that he has not been able to trace the whole life-history of the parasite, but he figures the spores. The disease is very common in Europe, and in West Norway the author says it is almost impossible to find a Potato without it: at the same time the existence of a few of the pustules does not injure the tuber, and it is only when they increase enormously in wet soils or seasons, that they render the crop unsaleable. Moreover, even in bad cases—except in so far as insects or fungi have entered the diseased spot and destroyed the tissues—the parasitic *Spongospora* does not enter cells far below the surface, and the removal of the skin leaves the tuber good to eat. The matter seems to deserve further investigation. *M. W.*

PLANTS CERTIFICATED BY THE ROYAL HORTICULTURAL SOCIETY.—In your report of the Royal Horticultural Society's last meeting you report a First-class Certificate for double lilac *Primula Eva Fish*. Would you allow me to ask, Why and for what the certificate was granted? as we exhibited it in Birmingham Town Hall show six years ago, and it has been exhibited most years since, and so cannot be called new; and I should like to suggest to the Royal Horticultural Society committee that, when a certificate is granted to a plant the exhibitor should say who raised it, and how many years it has been known to the public, or has been in commerce, and then honour would be given to whom honour is due, instead of as it appears now. Certificates are granted to any one who chances to show it, and frequently it is passed as of their own raising. My attention was called last spring to a First-class Certificate granted to a semi-double zonal scarlet *Pelargonium Paul Carbone*: this variety had been long enough in our possession to grow it thoroughly, try it, and discard it as useless. When will the Royal Horticultural Society committee wake up and grant it a certificate presumably as a new sort? I could readily enumerate many other cases, but this will suffice to show the value or valuelessness of the Royal Horticultural Society's certificates as at present granted. *John Pope.*

CHRYSANTHEMUM JUDGES.—I shall not imitate the verbosity of "Spade," and will refer him to his dictionary for a definition of the words "theorist" and "practical." As regards being a disappointed exhibitor my best reply is—I have been awarded a goodly number of 1st and 2nd prizes at some of the recent shows. The necessity for practical men as judges I contend is due to the fact that to make a man a good judge he should possess a thorough knowledge of the characteristics of the different varieties he is called upon to adjudge to enable him to arrive at a correct decision. Wherever men of ability, as Messrs. Molyneux, Mease, Archard, and Douglas are appointed the utmost confidence amongst exhibitors prevails. Questionable awards have been very frequent of late. I am glad, however, that at last it has come to be a question of "the writing on the wall." In the future I myself shall certainly require to be furnished with the names of judges beforehand, and if "Spade," or indeed anyone in whom I have not sufficient confidence as a *Chrysanthemum* judge is appointed, I shall not be an Exhibitor.

A RIDGE-AND-FURROW-ROOFED ORCHID-HOUSE.—There has been a great deal written from time to time in favour of or against ridge-and-furrow-roofed, or, as some choose to call them, Paxton-roofed plant-houses. After weighing the opinions on both sides it seems to me that the advantages claimed for the ridge-and-furrow principle are outnumbered by the disadvantages, so far as ordinary greenhouses or conservatory structures are concerned, the extra cost of construction and ultimate maintenance being among the chief objections. But how far the argu-

ment affects hothouses for special kinds of plants such as Orchids, does not appear to have been considered. I had not met with an Orchid-house built on the ridge-and-furrow principle until the other day, when at St. Albans I found that Mr. E. Sander is building a huge Orchid-house, which is to be devoted to *Cattleya* and *Laelia* culture, and the roof of the house is constructed quite on the ridge-and-furrow principle. Mr. Sander has not adopted this principle in ignorance of what has been said for and against it. He knew all this, and yet he maintains that for the special culture of Orchids, and particularly *Cattleyas*, such a roof is advantageous for several reasons which appear obvious. He contends that by the roof of a plant-house being interrupted in such a way as a ridge-and-furrow is by dips and rises, the sun never strikes the plants so fiercely as under a plain roof, but that every moment almost the shadows of the rafters and sash-bars are passing over them. Hence it is clear that the plants will not need to be so heavily shaded while they can enjoy the maximum amount of light. This, to me, seems a very feasible argument, and one that should be considered, as it is well known that in *Cattleya* culture the error is more often made in shading too much than otherwise. Mr. Sander proposes to shade the plants when necessary by awnings stretched under the roof inside so as to break the sun's rays on the brightest days. The atmosphere of the house in the winter will be influenced by the ridges and furrows as the ascending warm currents will be broken in rising, and so become more equally distributed. One of the difficulties in ridge-and-furrow roofs has been the rain gutters, but this, as well as the clearing away of collected snow has been considered. The ridges and furrows run across the house, not longitudinally, as is commonly the case; and from its position with relation to the sun the intermittent shadows from the roofs will pass over the plants in the way described. The house is 300 feet in length, by 26 feet in width. The width of each transverse span is 12 feet, and the height of the ridge is about 15 feet from the floor line. The pitch of the spans is not very sharp, but quite enough to shoot water off quickly, while provision is made to prevent drip by grooved sash bars. One side of the house runs at right angles to numerous span-roofed houses, each 300 feet long, while the outer side is glazed. There are two rows of handsome supports on either side of the central stage, which will be raised in the usual way in the centre with a bed beneath for evaporating material. The side stages are supported on arched walls, the reason for this being that bricks retain more moisture than wood, and give it out slowly. The pathways are trellised with wood, and beneath them are the trenches for the hot-water pipes—a principle that Mr. Sander has adopted in all his new houses, as he has proved it the best plan. There are four rows of pipes beneath the paths all round the house, four beneath the central stage, and one above the plants on both sides of the house, in order to circulate the air above the plants on the side stages. This heating power will be augmented by the heated air passing from the numerous houses that run at right angles to the new *Cattleya*-house, for as these are all built on a sloping level with a fall of several feet, the moisture-laden heated air from these houses will obviously rise to the highest end, and so into the *Cattleya*-house. It is indeed a noble house, and one that would repay a visit by all about to build an Orchid-house, as they would be sure to gather hints upon construction—the little things, in fact, that both house builders do not think of. They will see that no paint is used, but all the wood is the best Pitch Pine, varnished, and will also see that the particular evil guarded against is that of having, as is too often the case, the hot-water pipes too near the plants, which is, no doubt, the ruin of many Orchids. This house being the latest addition to this vast establishment—a veritable village of glass—it is, of course, the outcome of the experience the owner has gained during the many years he has been engaged in building for himself his houses and his great business. *W. G.*

SANITARY EFFECTS OF TRANSPLANTING.—It not infrequently happens that a disease assaults some choice plant which one would give much trouble to preserve. It may be a really scarce plant, or one that has some special association connected with it—perhaps the gift of a departed friend, or the happy "find" on some distant mountain top—the recollection of which is a constant pleasure; and to witness the growing sickness of our favourite from the attack of a destructive fungus without knowing how

to cure it is exceedingly vexatious. I observe that the usual advice is—destroy it at once, or it will affect others. But this requires much courage and self-denial to carry out, and I am not sure that to recommend such drastic treatment is in every case wise advice. Certain I am that he who has such an afflicted favourite will be thankful for any suggestion which offers a chance of success. Let me recommend transplanting it to a new soil and a new situation. That disease will very often disappear by this treatment is absolutely certain, as any one accustomed to introduce diseased plants into his garden for the sake of studying the features of the disease perfectly well knows. I may give two examples of the curative effects of transplanting in illustration of this. Some years ago I had in a border some clumps of Star of Bethlehem (*Ornithogalum umbellatum*), the leaves of which were annually destroyed by a black mould, *Heterosporium ornithogali*. I removed them to another situation in the same garden a hundred yards distant, and the fungus has never appeared on them since. The second case is that I saw in a friend's garden six miles from here: some Chives (*Allium schoenoprasum*) badly suffering from a severe attack of *Puccinia mixta*, and begged some to bring home to plant near my Onion bed, to see if the Onions would catch the disease. The result was that the Onions did not take the disease, and the Chives were cured. *W. Phillips, Skerresbury.*

AN EXCELLENT VARIETY OF POTATO.—If "North Norfolk" would try the Mayor Potato as a field cropper variety it might suit him. It has been raised by Mr. James Anderson, Mains of Parkhill, Arbroath. This gentleman is working with Mr. Nicoll, the raiser of the Champion, in raising and selecting new sorts from seed. This one was selected from a batch of seedlings and promises to become a very useful variety. It is flattish oval in shape, grows to a good size, and is a very heavy cropper. The skin is roughly netted, flesh white and of splendid quality when boiled. It is an improvement on *Magnum Bonum*, and, unlike that sort, can be used when dug. Those who grew it last year speak very highly of it. Some weeks ago I saw the produce of Mr. Anderson's seedlings, but this one is far in advance of the other and promises to become a standard sort. *W. R.*

FREESIAS.—With regard to your correspondent's ("R. H. L.") remarks on the *Freesia*, I have also observed the same tendency of the bulbs to remain dormant; they will, however, usually start again the following season. I suggest as a slight alteration of his treatment to allow the bulbs to ripen slowly in a temperature similar to that in which they bloom best, say 55° to 60°, keeping them in the old soil until they are repotted, which should be done in successional batches during June and July, but not later. The rest of my treatment of the bulbs accords entirely with that of "R. H. L.," and with what I consider good results, some of the spikes this season having carried nine or ten flowers at the top, with two and three spikelets bearing five and six flowers each, all of which expanded when left uncut. *G. A.*

APPLES TO PLANT IN NEW ZEALAND.—Seeing an inquiry in your columns from Mr. J. N. Lawless (p. 37), I venture to offer my advice to him. First, as to the number of Apples he contemplates planting; the choice seems to be far too great, unless he wishes to plant a very large area of land. With so many varieties there would not be enough fruit of each on a small area to make it worth while carefully gathering and packing the fruits; added to which there are, I would venture to say, not twenty-four varieties of Apples which would be suitable for his purpose. I should recommend the following, which, I think, would pay him far better than a larger number:—*Dessert*; *Ingram's Improved Herefordshire Pearmain*, *Golden Reinette*, *Ribston Pippin*, *Cox's Orange Pippin*, *Sturmer Pippin*, *Cooking*; *New Northern Greening*, *New Caldwell*, *Dumelow's Seedling*, *Alfriston*, *Bramley's Seedling*. There is an Apple which is extensively grown in New Zealand called *Bismarck*, but from what I have seen of it I should not say it is not very good for long carriage, as the skin being thin and delicate, it would probably show bruises. *A. H. Pearson, Chilwell, Notts.*

ODONTOGLOSSUM CRISPUM (BLUNTI, ALEXANDRÆ). In your obituary notice last week of Mr. John Day you credit him with being the first to

flower the above-named plant. This is a mistake. It was originally introduced by Messrs. Low & Co., of Clapton, from whom we both procured plants; but my late gardener, Mr. Wilson, was successful in blooming the first one, and it was exhibited by him at one of the meetings of the Floral Committee, and received a First-class Certificate under the name of O. Blunti. Mr. Bateman subsequently named it O. Alexandra, and Mr. Thistleton Dyer afterwards proved it to be synonymous with O. crispum, Lindl. W. Marshall, Bewley.

SOCIETIES.

MANCHESTER HORTICULTURAL IMPROVEMENT.

At the meeting on Thursday evening, January 19, Mr. Leo H. Grindon delivered an address on "Trees adapted for Manchester." Mr. Bruce Findlay, President of the Society, was in the chair.

Mr. Grindon, who has recently had an accident to his right arm, and is consequently disabled from writing, apologised for not coming before them with a carefully prepared paper. He said that, although the majority of those present lived in the country, he supposed there was not one of them to whom the subject of town gardening and town trees was not of some interest. What he was about to say would have reference to Manchester, because trees in towns would be far too comprehensive a subject to be dealt with at this meeting. But his remarks would be founded on the observations made in other large manufacturing towns, including Leeds, Sheffield, Halifax, Huddersfield, Wigan, Bolton, and Bury. Their main object, of course, is to make the city more healthy for human beings, but they could not do that without garden-loving folk benefiting from it, because wherever human beings do best plants do best. The purification of the atmosphere was, however, by no means the only thing that required attention in this matter, for the nature of the soil, the influence of drainage and noxious gases must be taken into account. He was not going to include Whalley Range and Alexandra Park in speaking of Manchester, but should confine his remarks to those districts which are more or less affected by smoke. We can never expect to have in Manchester such noble trees as they have in London and Bath. Nor can we expect to see Planes here such as those which ornament the great squares in London, nor the Elms which do the same for Bristol, Noxious Vapours Associations notwithstanding, for the simple reason that the climate of this district is unfavourable to their growth. If, then, we cannot have the majestic Oaks, Elms, and Planes, we must see whether there are not fifty other trees which, though of smaller dimensions and less ambitious, will, by a little judicious mingling, afford us as much delight as the grand old Oaks and Chestnuts. The plants to be considered fall under three heads:—1. Those which have already grown in Manchester, and are now doing well. 2. Those which refuse to grow altogether, which he need not dwell upon. 3. Those which are worthy of a trial; and it was to these he desired to direct their particular attention. The Balsam Poplar, Black Poplar, and the Hawthorn are amongst those which will grow here. He wished they could have seen the Hawthorn which he had in his Rumford Street garden three years ago loaded with its summer snow, and such a delightful spectacle that many persons stopped to admire it. Willows also, when they have a fair chance, do well. The common green Willow has had a wonderful growth in his little garden in Cecil Street, Greenheys, during the last four years. The common Sallow may also be included in the list of those which do well.

He now came to trees which are waiting to be made more use of than they have been hitherto. Amongst these are the Fig tree, the Mulberry and the scarlet-berried Elder. Of the last named, he could say that he never saw a finer specimen than one that was growing almost in the midst of the Wigan smoke three or four years ago. He had seen this tree cultivated in nurseries, but why not introduce it within two miles of the Exchange? The common Siberian Crab is also very well adapted for town culture. The Aralia spinosa, commonly called the Angelica tree, blooms abundantly in the Botanical Gardens at Old Trafford, and he had seen it doing wonderfully well amongst the smoke of Bristol. Then there is a tree known as "the tree of heaven" (Ailantus), which is exceedingly well adapted

for towns, being proof against both smoke and insects. We must be thankful if we can get fine foliage in town; never mind the flowers, and if we cannot have what we would like, to make the best of what we can have. The Mountain Ash, White Beam, and Horse Chestnut were amongst others he could recommend for Manchester. Some thirty or forty years ago there was a noble-looking Horse Chestnut growing at the foot of New Bridge Street, whose branches spread almost into the middle of the roadway, and was every year laden with flowers, but it had to give way to street improvements. If it would grow there he should think it would grow at a similar distance from town. The Tulip tree is another capital town tree, and there was one which did remarkably well in a garden in Arlington Place, Oxford Road, until its roots were damaged by the men employed on some drainage works there. The Nyssa, or Tupelo, has also proved itself able to stand the injurious influences of a town atmosphere. The Almond will also flourish and produce a load of bright pink flowers in early spring. Of the Lentisk-leaved Ash Mr. Stansfield had a good specimen in his garden on the edge of Kersal Moor, where it no doubt gets the full flavour of the Salford smoke. Of the sweet Bay-leaved Willow, which grows wild about Marple in abundance, there are two beautiful examples in Plymouth Grove. Turning now to shrubs, he said the yellow Azalea may be seen at many points along Stretford Road, and close to the church of the Holy Name, Oxford Road, there is a grand specimen of the American Bramble, which is covered with bright red flowers every year. There is also one in Mr. George Milner's garden, close to Harpurhey, which seems to hold its own like a sturdy Briton who was determined not to be driven from his position. In his own garden, in Rumford Street, a Rhododendron flourished wonderfully, and in his present garden in Cecil Street there is a spotted Laurel (Anechu) growing and thriving. Every autumn a house in Burlington Street, Greenheys, is made beautiful by a white Jessamine which is growing there. If we want glorious foliage, the Grape Vine is an admirable plant for the purpose, and he was surprised that it is so much neglected as a decorative plant for gentlemen's gardens. He next referred to the Pyrus japonica and the Sunflower, of which latter a splendid specimen is to be seen every season in Grosvenor Street, London Road: common Goards and Pumpkins, which he had successfully cultivated in his Rumford Street garden, and other varieties.

Mr. Stansfield said he could not recommend the Mountain Ash, the "Service tree," Horse Chestnut, or Lime, for towns.

Mr. Upjohn said he thought the Lime could be made to succeed under certain conditions. The Horse Chestnut does well at Worsley. Manchester City News, Jan. 21.

THE WEATHER.

THE PAST WEEK.

The following summary record of the weather for the week ending Jan. 23, is furnished from the Meteorological Office:—

"The weather has continued cloudy or dull generally, with a good deal of mist or fog locally. Towards the end of the period, however, brief intervals of exceptionally fine weather for the season were experienced in some parts of England.

The temperature was low during the earlier part of the period, but subsequently rose decidedly; and, on the whole, the average for the week has not differed materially from the normal. The highest of the maxima, which were generally recorded on the 20th in Ireland, and on the 23rd, varied from 51° in 'Scotland, N.' 'England, S.W.' and the 'Channel Islands,' to 55° in the Midland Counties of 'England, S.W.,' 56° in 'Ireland, N.,' and 58° in 'Ireland, S.' The lowest of the minima, which were recorded either on the 18th or 19th, ranged from 12° to 18° in Scotland, from 18° to 26° in England, and from 25° to 27° in Ireland; in the 'Channel Islands' the lowest reading was 31°.

"The Rainfall has been considerably less than the mean in all districts.

"Bright sunshine has again been very deficient in most districts, the percentage of the possible amount of duration ranging from 7 to 23 over the greater part of the kingdom; in 'Scotland, E.' however, 32, and in the 'Channel Islands' 46 were recorded.

MEAN TEMPERATURE OBSERVED AT CHISWICK DURING THE WEEK ENDING FEB. 4. (AVERAGE OF FORTY-FOUR YEARS.)

Table with 2 columns of dates and corresponding mean temperatures in degrees Fahrenheit, ranging from 38° to 39°.

Accumulated temperature indicates the combined amount and duration of the excess or defect of temperature above or below 32° F. for the period named, and is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

TEMPERATURE.

Table showing accumulated temperature for various districts (Principal Wheat-producing, Principal Grazing, etc.) with columns for Day-degrees and differences from previous periods.

RAINFALL. BRIGHT SUNSHINE.

Table showing rainfall and bright sunshine for various districts, including Principal Wheat-producing, Principal Grazing, etc., with columns for inches, tenths of an inch, and percentage of possible duration.

Obituary.

PROF. DE BARY.—We grieve to say that the death, on the 19th inst., of Professor de Bary, of Strasburg, is announced. As an anatomist, and an authority on the morphology of fungi, De Bary was unrivalled, while his personal qualities endeared him to all with whom he came in contact. The Botanical Institute at Strasburg—a palatial edifice—was constructed under his superintendence.

SHARPE'S SEEDS.

NEW BROCCOLI—SHARPE'S MONARCH.

This fine Broccoli was raised by a Gentleman's Gardener in the Midlands, and judging from the reception it has received in the Birmingham and other important markets, it will, no doubt become the kind for market purposes, being thoroughly reliable, and producing large pure white heads, commanding prices ranging up to 9s. per dozen. The flower is well protected by the foliage until ready to cut, when the leaves fall back and expose a magnificent head of from 12 to 15 inches in diameter. The heads are very firm and clear, and of great weight, and entirely free from mossy or discoloured heads. Its season is from the middle of March to the end of April, and we have no hesitation in recommending this as being one of the best Broccoli sent out for years.

Price, 2s. 6d. per Sealed Packet.

VEGETABLE AND FLOWER SEEDS DIRECT FROM THE FIELDS!

CANNELL'S NATURAL

NATURE makes it an IMPERATIVE FACT that KENT possesses a more favourable CLIMATE and SOIL than any other county in England (perhaps even in Europe) for the production and RIPENING of Seeds, also in COLOURING, BRIGHTNESS, PLUMPNESS—the Force of Life or Germinating Power stronger to withstand unfavourable weather, and far MORE PROLIFIC. Coming from a calcareous subsoil, the thorough change (SO ESSENTIAL) makes the yield of our seeds marvellously rich and productive. Further, we are determined that the purchaser shall have the CHOICE and ADVANTAGE of Seeds DIRECT from the ACTUAL GROWERS, and thus avoid the risk and deterioration where seeds are bought

CANNELL'S ADVANTAGES.

and sold half-a-dozen times between the SAVERS to the SOWERS. Our Illustrated Catalogue for the Garden contains a vast amount of invaluable information on high-class culture and gardening, and enables amateurs to be supplied with the BEST of all WANTS FROM THE GROWERS. Replete with 550 Engravings, Two large Views of our SEED FARM, The TWO HARD WORKERS, and Three magnificent COLOURED PLATES of New and Improved Plants and New Invaluable Vegetables—so important to successful prizetakers. The whole are really a gift to the nation.

Post-free to Previous, Present, and Coming Customers.

H. CANNELL & SONS, SWANLEY, KENT.

CHARLES SHARPE & CO.'S SPECIALTIES.

QUEEN.

A grand Blue Marrow; height 2 feet. Pods large, deep green, with large, green, deliciously-flavoured Peas. It is so continuous a cropper that a constant supply may be obtained by it alone after the first crop is ready.

3s. per Pint Packet; 1s. 6d. per Half-pint Packet.

CHARLES SHARPE & CO., SEED MERCHANTS, SLEAFORD.

Price in box, 8 6
Post-free 6d. extra.

"MYTICUTTAH"

(REGISTERED).

PATENTED in GREAT BRITAIN, FRANCE and GERMANY.

As the S. M. Co.'s "Standard" Tree Pruner is admitted to be the best Pruner for work a
distance from the ground, so will the two "MYTICUTTAHS" prove the handiest and most
powerful for Pruning and Trimming close to the ground, such as the removal of shoots from roots
of trees; also Shrubs, Fruit and Flower Bushes, Vines, and other climbing plants, &c. Their
construction enables prickly Shrubs and Bushes to be Pruned without lacerating the hands or
wrists, even if gloves are not worn. They will with ease cut the hardest wood growing without
injuring the part left by splitting and drawing the sap several inches up and causing decay, as
other implements are known to do.

For Illustrated PRICE LISTS of above and other NOVELTIES in PRUNING TOOLS,
FRUIT and FLOWER GATHERERS, &c., apply to the

STANDARD MANUFACTURING COMPANY,
ST. ALKMUND'S CHURCHYARD, DERBY;

Or to their Agents, the Principal Ironmongers and Seedsmen at home and abroad.

Large size.
Price in box, 9 6
Post-free 7½d. extra.

Length 18 inches, weight
1½lb. Will cut a branch
½ of an inch in diam.

RICHARD SMITH AND CO., Nurserymen and Seed Merchants, Worcester.

GANNELL'S BEGONIAS.

BOTH our **DOUBLE** and **SINGLE** varieties are well known to have attained a much higher standard of perfection—colour wider and brighter—than any other strain, for the reason that we cross them more scientifically and practically, with the positive result, as pronounced by the greatest critics and connoisseurs, that the display in full flower in our eight houses was “SIMPLY WONDERFUL and UNEXPECTED.” We have hundreds of Testimonials confirming this fact. Our Tubers are now an unusually interesting sight, and our Seed is by far the best we have ever offered.

Double and Single, 2s. 6d. per packet.
SEND FOR OUR CATALOGUE.

J. W. TAYLOR, Esq., Ann Street, Dundee, October 21, 1887. “I gained 1st prize with your Single Begonias, both in Downhill and Dundee Shows, and there was not one at either that could come within 3 inches of the size of my flowers. I have taken 1st prize from all the amateurs for three years. I was also 1st for Bronzes and Fuchsias, all got from you. My collection of Begonias from you is a show in themselves, and a talk over the country. Several gardeners, who have a good collection themselves, came a great distance to see them, but all admitted they had nothing to be compared to mine.”

SWANLEY, KENT.

FOR SALE, CHEAP, 16,000 OAKS, 6 to 12 feet, 30s. per 100; 800 CHESTNUTS, 10 to 12 feet, 40s. per 100. Cheaper for large quantities. Apply to **THOS. HEDDLEY**, The Gardens, Putteridge Park, Luton, Beds.

W. ATLEE BURPEE & CO., 133 CANNON ST., LONDON, E.C.

Spring, 1888.
NEW WHITE ROUND POTATO,
WEBBER'S "EARLY WHITE BEAUTY." Awarded First-class Certificate, Royal Horticultural Society, September 21, 1887. The many testimonials received from well known authorities speak so well for the excellence of this splendid new white-skinned Potato that a lengthy description is unnecessary; in short, it possesses every good quality. It is of handsome appearance, with shallow eyes, and the superior of the "Beauty of Hebron" both for quality and productiveness, whilst its dwarf habit and extraordinary quickness of maturation make it invaluable for early work. It has been tried on all kinds of soil with most satisfactory results, producing in every case a fine crop entirely free from disease.

TESTIMONIALS.
 From Mr. CHAS. ROSS, The Gardens, Welford Park. "I am very much pleased with the Early White Beauty Potato you sent me for trial. It cooks dry and floury, and the flavour is excellent."
 From Mr. JAMES McCULLUM, Gardener to Lady H. Warde, Knaitley Hall, Leigh. "The six tubers of Early White Beauty Potato you sent me for trial I cut into fifty sets, having only one eye to each set. Lifting them the second week in August, I found the produce to weigh 48 lb. of nice even-sized tubers, and when cooked were of excellent quality. It is certainly better than any early we have grown, and I advise every one to give it a trial."
 From Mr. GEORGE GOLDSMITH, F.R.H.S., The Gardens, Floore House, Weedon. "The Early White Beauty Potato you sent me in the spring for trial turned out to be a good cropper and of excellent quality, and the tubers of uniform size. I think when well known it will be grown extensively as one of our earliest varieties. It will make a grand variety for exhibiting, and will be useful for table as well, not like many of our varieties, fit for exhibition only."

From Mr. S. LOCKYER, Gardener to Thomson Hankey, Esq., The Grange, Shipbourne. "The new Potato Early White Beauty, of which you sent me a few tubers last spring to try, I am very pleased with. It is a splendid cropper, and of very best quality."
 From Mr. W. MIST, Ightam, Sevenoaks. "I have much pleasure in testifying to the excellence of your new Potato. I planted the sets on May 20, and showed the produce in my winning collection at Dover on August 27."

See Testimonials continued next week.
 Price—1 lb., 1s.; 7 lb., 6s.; of

CREEPERS FOR WALLS.—By planting what is suitable, an ugly object may easily be made beautiful. Descriptive *LIST* and advice Free.
RICHARD SMITH AND CO., Nurserymen and Seed Merchants, Worcester.

Sharp's Victor Potato.
CAUTION.—Messrs. **CHARLES SHARPE & Co.**, Sleaford, Lincolnshire, wish to Caution Buyers of the above Potato, to see that they are supplied with the true variety, as many spurious stocks are offered under the name of **VICTOR**, and great disappointment has ensued.
The true **VICTOR**, as sold by Messrs. Charles Sharpe & Co., is a medium-sized, flattish oval, smooth-skinned variety, with very shallow eyes and yellow flesh—extremely early, producing Potatoes fit for use in 8 to 10 weeks from planting. Large quantities of later rough-skinned, round, white-fleshed Potatoes have been sold for it by some houses.
To secure the true kind, apply either to **CHARLES SHARPE AND CO.**, or to a Firm supplied direct from them.
CATALOGUE on application.
CHARLES SHARPE AND CO., Seed Merchants, Sleaford, Lincolnshire.

CANNELL'S BOUND CATALOGUES.

THE demand for our Cloth-covered Catalogues has exhausted our usual number, and we beg to intimate that another supply will be ready and sent on as quickly as possible, and we hope that all requiring such will send in their orders at once.

CANNELL & SONS, SWANLEY, KENT.

Mr. J. G. BLACKMAN, Hatherley Cottage, near Cheltenham, January 27, 1888.
"I will thank you to send me on four copies of yours, the best of all Catalogues for the garden."
C. HOLDEN, Esq., Oxford Road, Reading, January 28, 1888.
"Catalogues to hand, for which I return you my best thanks. The plates are splendid—so natural—quite different from the dubs we get from other firms."
Dr. MEAD, Mortimer House, Bishops Lydeard, Taunton, January 25, 1888.
"Thanks for *Floral Guide*, a book where infinite variety never stales, and which has occupied me for hours during the past year. Debit me with it. Send me one every year. Cannell's Guide is the cheapest and most interesting shilling's worth extant."
Mrs. SALE, 29, Defoe Road, Tooting, January 28, 1888.
"Thanks for Catalogues. Will thank you to send another to enclosed address; 1s. 3d. enclosed."
CATALOGUES RECEIVED.—Messrs. H. Cannell & Sons' *Complete Illustrated Floral Guide* for 1888, consisting of over 300 pages, sent us by carrier is a marvel, even amidst wonders from America. Horticulture is a power in the realm, or such guides could not exist.—*Lloyd's Newspaper.*

"PRESIDENT CARNOT."
New and Select Stock of
BRUSSELS SPROUTS.

JOHN ETHERINGTON DIXON, having
purchased the entire Stock of this extraordinary variety
from Mr. JOSEPH BENTLEY, purposes sending it out for Season
1888. It has proved, by all who have grown it, to be the best
extant for size of knobs and habit of growth. It grows similar to
a pyramid, and has been selected with the greatest care possible,
so that it may be depended upon as something specially good.

Testimonial—from Mr. Albert Welf, Gardener to
Nathaniel Clayton, Esq., J.P., Eastcliff Gardens, Lincoln—
"Sir,—Your strain of Brussels Sprouts is the best in cultivation.
I tried it the first year, alongside three of the leading strains,
but it proved so much superior to the others that I have grown
no other since. The exhibit of your strain of Brussels Sprouts
on my Chrysanthemum Show will not easily be forgotten by
those who were present, drawing high encomiums from the
judge, Mr. J. Wright, Journal of Horticulture."
To Mr. Joseph Bentley, January 5, 1888.

[The above is only one out of many received.]
Price 2s. 6d. per Packet; free by post, 3s. stamps.
Usual discount to the Trade.

bags. Lots under 10 cwt., 4s. per cwt. A 1 cwt.
sample bag sent, carriage paid, to any Station in England on
receipt of P.O. for 5s.

Extracts from Twelfth Annual Collection of Reports:—
NATIVE GUANO FOR POTATOS, VEGETABLES, VINES,
and FRUIT.—G. COUSINS, Walton-on-Thames. "Used for
Potatos. Result: very excellent crop; remarkable size and
good quality. Can highly recommend it."
D. WILLIAMS, Head Gardener to Rt. Hon. Lord Wimborne,
Canford Gardens, Wimborne. "Used for Vines, Peaches,
Strawberries, flowering plants, kitchen garden crops, with very
good results. First-class manure for pot Strawberries."
NATIVE GUANO FOR ROSES, &c.—T. ST. CLAIR, Rose grower
by appt. to H.R.H. the Princess of Wales, Strawberry Hill. "Used
for standard and dwarf Roses. Result: excellent growth,
fine bloom, and perfectly free from blight the whole season."
A. F. HARRON, Royal Horticultural Soc., Chiswick. "With-
out doubt a very valuable manure, and easy of application."
Orders to the NATIVE GUANO CO., Limited, 29, New
Bridge Street, Blackfriars, London, E.C., where Pamphlets of
Testimonials may be obtained. Agents Wanted.

Are the Best in the World.

DANIELS' DUKE OF NORFOLK.

A magnificent New Variety, immensely prolific. Handsome dark green fruits, 18 to 24 inches long. Price 2s. 6d. and 5s. per packet.

DANIELS' MASTERPIECE.

A splendid New Variety, exceedingly handsome. First-class for Exhibition, and unexcelled for table. Price 2s. 6d. and 5s. per packet.

DANIELS BROS., The Royal Seedsmen, **NORWICH.**

VEITCH'S TWO NEW CARROTS MATCHLESS & MODEL,

THE BEST for EXHIBITION, TABLE USE AND PROFIT.

VEITCH'S MATCHLESS SCARLET CARROT.

A splendid strain of the Intermediate type, but heavier cropping, earlier, and far superior in quality and shape to the old variety. Per Ounce, 1s.

VEITCH'S SCARLET MODEL CARROT.

The finest and most perfect type of the Stump-rooted class. Remarkably early, regular and symmetrical in shape, and of a bright glossy scarlet colour. Per Ounce, 1s. 6d.

"I have sent you six each of your Matchless and Model Carrot, grown from seed you sent me last spring. Two Carrots that put all others completely out of cultivation for main crop varieties, not only for weight, but for quality far exceeding any other sort. I think the public should know this.—CHAS. PENNY, The Gardens, Sandringham, October 25, 1887."

For full descriptions of the above and other Choice Novelties, see SEED CATALOGUE for 1888, forwarded Post Free on application.

JAMES VEITCH & SONS,
ROYAL EXOTIC NURSERY, CHELSEA, S.W.

WEBBS' "STERLING" SPECIALTIES

WEBBS' KINVER GLOBE SAVOY.
The heads are globular in shape, solid, and fine flavoured.
1s. per Packet, post-free.

WEBBS' EMPEROR CABBAGE.
Lord DERBY's Gardener says:—"Webbs' Emperor was grown with four other sorts, and was considered the best of the lot."
6d. and 1s. per Packet, post-free.

WEBBS' MAMMOTH RED CELERY.
Mr. J. OWEX says:—"I gained First and Second Prizes with your Mammoth Red Celery at our show."
6d. and 1s. per Packet, post-free.

WEBBS' CRITERION LETTUCE.
Mr. J. MUIR says:—"Your Criterion Lettuce is a beauty—the best of all."
1s. per Packet, post-free.

WEBBS' JUBILEE TOMATO.
The Right Hon. J. CHAMBERLAIN'S Gardener says:—"It is one of the best I ever grew. I shall grow it again."
1s. 6d. and 2s. 6d. per Packet, post-free.

WEBBS' MAY QUEEN BROCCOLI.
Mr. F. ROBERTS, Prestwood Gardens, says:—"I consider it the best winter variety yet introduced."
1s. 6d. per Packet, post-free.

WEBBS' BANBURY ONION.
Mr. J. MUIR says:—"Webbs' Banbury is the best for the main crop, and none can equal it for exhibition."
6d. per Packet, 1s. per Ounce, post-free.

WEBBS' MATCHLESS B. SPROUTS.
Mr. W. IGGULDEN says:—"Webbs' Matchless proves to be of great merit, producing an abundance of sprouts."
6d. and 1s. per Packet, post-free.

WEBBS' WORDSLEY WONDER PEA.
THE GARDEN says:—"This Pea merits all that can be said in its favour."
3s. per Quart, post-free.

See **WEBBS' SPRING CATALOGUE,**
Post-free, 1s. Gratis to Customers.
ABRIDGED EDITION Gratis and Post-free.

WEBB & SONS,
WORDSLEY, STOURBRIDGE.

B.S. WILLIAMS' NOVELTIES FOR 1888.

THE FOLLOWING SPLENDID NOVELTIES are my own introductions for 1888, and are now offered for the first time. Sold only in Sealed Packets bearing my Trade Mark:—

A GERATUM, "ADA BOWMAN" (new).

This new variety was raised at Hylunds Park three years ago. It is without doubt the finest Ageratum grown for bedding purposes. It blooms in masses from the time of planting out until it is cut down by the frost, and requires no pegging down, as it is only 9½ inches high; the trusses measure from 6 to 7 inches across. It is of a very effective and telling delicate blue colour.

It is a most valuable acquisition when propagated in pots in the autumn for early winter flowering. Its freedom in blooming is so pronounced that each pot is quite a ball of flower, and continues so to the middle of January.

Per Packet, 1s. 6d.

PRIMULA SINENSIS FIMBRIATA, "MAGENTA QUEEN" (new).

This new variety is of very compact habit of growth, very vigorous and robust; the leaves are of a dark green colour. The blooms are very large, measuring upwards of 2½ inches in diameter; they are of very good substance and a bright magenta, with a small bright lemon eye. It is quite a new colour in Primulas, and its distinctness is very pronounced when associated with other kinds.

Per Packet, 5s.

STOCK, INTERMEDIATE, WILLIAMS' "CRIMSON GEM" (new).

This variety, on account of its charming and decided colour, is an acquisition of considerable merit, as it is a great advance in richness and brilliancy of colour upon any known kind of Stock. It will be found very serviceable for spring bedding, window boxes or pots, where it will produce a wonderfully fine and pleasing effect. It is of a dwarf compact habit; the central spike and lateral branches produce a great profusion of very rich crimson blooms of very large size.

Per Packet, 2s. 6d.

MELON, HAMSTEAD PARK SEEDLING (new).

This fine new variety is a cross between *Golden Perfection* and *Victory of Bristol*. The raiser speaks very highly of it, and says that it does as well in a pit as in the Melon-house. It is a first-rate setter and a very strong grower, and never shows any sign of canker at the collar. It is round in shape, very handsome, and beautifully netted. The flesh is of a very pale scarlet colour, about 3 inches in depth, with very delicious flavour. The fruit weighs from 4 to 8 lb. each.

Per Packet, 2s. 6d.

ILLUSTRATED

SEED CATALOGUE FOR 1888

Is now ready, and will be forwarded Gratis and Post-free to all applicants.

As a Supplement TO THE GARDENERS' CHRONICLE FOR Next Week, Feb. 11, WILL BE Published an Ink-Photograph, REPRESENTING LÆLIA ELEGANS VAR. NYLEPHTA. Grown and Photographed by H. Measures, Esq.

THE Gardeners' Chronicle.

SATURDAY, FEBRUARY 4, 1888.

STRAWBERRIES.

ONE is continually asked nowadays for an earlier Strawberry than Black Prince or Vicomtesse Hélicart de Thury, or for a later one than Eleanor or Elton Pine; and the seekers for this kind of information seem to think that if there were such, they would, as the phrase goes, supply a long-felt want, and be the means of lengthening the somewhat brief Strawberry season.

So far so good; but has it never occurred to the seekers after these earlier and later varieties that there would be some very great difficulties in growing them to perfection, supposing that they could be obtained? I do not mean to say we shall never possess them, for there is scarcely any limit to possibilities in that way, and even now there are varieties which claim to be earlier than even Black Prince. What it is desirable to point out is the fact, that the earlier the plant puts forth its blossoms the more surely will they be destroyed by the frosts of May; or, in other words, we have in Black Prince as early a Strawberry as climatic circumstances will permit. The frost, except in very exceptional seasons, always destroys the most promising and largest bloom of what is termed the king berry—i.e., the berry which originates earliest, and is the lowest on the flower-scape. Artificial protection is here left out of the question; the best berry is lost, and others, somewhat later, take its place. If the flowers appeared much earlier, we should most likely lose the whole or the greater part of the blooms by frost, unless we had a plant of great vigour and hardiness, such as we may possibly obtain in an improved Black Prince or Vicomtesse Hélicart de Thury. The earliest Strawberries we now possess are certainly the hardest grown, and exhibit a true instance of the survival of the fittest.

It may also be observed that our earliest varieties do not produce large berries, but medium-sized ones; indeed, the fruit of Black Prince may be classed as small. It takes longer to mature a large berry, hence the smallness of the early varieties, for even some of the large mid-season Strawberries flower as early in the

season as Black Prince, although the period that elapses from blooming to ripening in their case is much longer. Unless, therefore, we have a vigorous plant, and a comparatively small berry, our would-be earliest will be handicapped by the adverse influences of our climate before mentioned.

I may remark that young plants are constitutionally stronger, and hence with them we can and do obtain much earlier fruit than with old plants, the latter of the same sort being usually a week later in ripening their fruits.

As regards late kinds, another, though similar difficulty, presents itself. It may be noticed that most of our late Strawberries—Sir Charles Napier, Eleanor, Elton Pine, and many others—possess so much brisk acid flavour, as by some to be regarded as wanting in sweetness. This may be of great advantage, for the wasps (which usually appear in numbers at that time) are deterred by reason of the flavour from working such havoc amongst them—these pilferers being not impartial judges, but always choosing the sweetest and best-flavoured varieties; and whilst late berries of the sweet mid-season kinds are spoiled by wholesale, the more acidulous late ones are left untouched.

Again, late ripened fruit of the Strawberry is very liable to quick decomposition. Whether this is by reason of the immature ripening consequent on the great strain the plant has borne, oftentimes in hot, scorching periods, or whether it is a peculiarity of the berry at that season, I cannot say; presumably again climatic conditions have an effect in reducing the vital powers of the plant, which largely influence the ripening and keeping qualities of the fruit. From what has been said, therefore, it will be seen that to obtain a late Strawberry that shall possess good ripening and keeping qualities the plant should be endowed with much vigour, and be able to withstand in the fullest measure the effects of drought and long continued sunshine that we occasionally experience. If any raiser, therefore, is intent on raising a really good kind that shall be earlier or later than those we already possess, he will do well to bear the above facts in mind. *John Lovel.*

NEW OR NOTEWORTHY PLANTS.

ESMERALDA BELLA, *n. sp.**

This is a very unexpected discovery, as nothing like it was known in herbaria. I have to thank for this grand pleasure my old and indefatigable correspondent, Mr. W. Bull, whose No. 1022 it is among the Orchids sent me out of his large stores.

To give an idea of the plant, take a raceme of four flowers which combine the shape of those of *Esmeralda Cathartii* (though they are much narrower) with nearly the colours of those of *Esmeralda Clarkei*, and in lieu of the long narrow leaves of both species suppose very broad, very short shining leaves, which are unequally bilobed at the apex, one lobe being shorter, blunt, retuse, the other produced and dimidiate round outside, straight inside. The pollen apparatus is that of *Esmeralda Clarkei*. The colours are much finer and brighter, the side-lacinia of the lip are rounded on the anterior side, not angulate. The tumid multi-lobed mucriculate margin of the anterior lip is much broader than in *E.*

* *Esmeralda bella*, *n. sp.*—Folii brevibus quinquepollinibus prope pediculis latis, apice inaequaliter bilobis; racemo quadrifloro; bracteis bene evolutis; sepalis tepalibusque cuneato-oblongis obtuse acutis, labelli lacinia lateralibus rotundatis, lacinia media oblonga, margine papuloso lato, callo in basi rotundo parvo a basi ante apicem lineari pandurato, basi unilobato, antice quinquefido, callo globoso anteposito; columna trigona caudicula hippocrepica. Ex col. exc. W. Bull. *H. G. Rehb. f.*

Clarkei. The flower is very elegant. The spreading sepals and petals are all straight, light ochre with fine bars of warm cinnamon. The lip is white-coloured; side-lacinia with purple-brown stripes; mid-lacinia very broad, tumid; margin horse-Chestnut brown. The basilar rounded callus is white with brown spots. Then comes a long, longitudinal, tumid, ligulate body that extends to the front of the apex, where there is another semiglobular callus. Four furrows divide the anterior part, one furrow the superior end. The column is ochre coloured, full of eddish spots. Caudicula crescent-shape. *H. G. Rehb. f.*

LAELIA TRESSEDERIANA, *n. hyb. artif.*

Messrs. Heath & Son, Exotic Nurseries, Cheltenham, have sent me this lovely novelty. It is the result of a cross between *Laelia crispata* and *Cattleya Loddigesii*, raised by their junior partner, Mr. J. S. Treseder. The seed was sown in January, 1881, and on last Christmas day the flower expanded. It is a great pleasure to dedicate it to Mr. J. S. Treseder, who is, as I learn from Mr. Heath, very diligently engaged in hybridising in a good way. The bulb is fusiform, and may be compared to that of *Laelia crispata*. I have a pencil sketch before me, showing the sheaths still covering the bulb. There are two leaves, 5–6 inches long by 2 inches broad, cuneate-oblong, blunt acute. The peduncle is strong, and appears to have been two-flowered. The sepals and petals have the shape of those of *Laelia crispata*, but the petals are far less wavy; they are of an elegant light rose colour. Lip cordate at the very base, expanded, trilobed; side lobes spreading, blunt, triangular, much shorter than broad, triangular wavy mid-lobe, is deep rose coloured, covered with dark purple reticulations. The disc of the lip is light yellow, with white margins to the side lobes; there are some purple nerves on the basilar disc. Column white. Two broad rows of purple spots extend in front of the column under the fovea. Pollinia unequal. *H. G. Rehb. f.*

MAXILLARIA HÜBSCHII, *n. sp.**

This was discovered by Mr. Hübsch, a Sanderian collector, when in search of *Maxillaria Sanderiana*. It was introduced with this, and flowered with Mr. R. H. Measures, of Streatham. The plant is quite like that of *Maxillaria fucata*. The peduncle has a few inflated sheaths. Bract shorter than the ovary. Lateral sepals much rounded, like a goitre. Petals linear rhombic acute. Lip transverse, rhombic. There is a transverse yellow emarginate callus on the disc, and strigose hairs behind. Flower white, as large as that of *Masdevallia molitor* and *fucata*. Lip with mauve-purple margin inside, and two blotches of that colour and a few purple dots at the base outside. Column white, with nearly parallel mauve stripes in front. *H. G. Rehb. f.*

CATASETUM TAPIRICEPS, *n. sp.†*

Messrs. Linden, of Brussels, have just flowered a Brazilian *Catasetum* of a rather new shape. It may be compared generally to *Catasetum macroglossum*. Sepals green; petals brown; lip trigono-sacciform, free margin, neatly toothletted; side-lacinia revolute, mid-lacinia with a transverse emarginate keel not far from the margin. Colour orange. Column with a large apex, leaning over, reminding me of a Malayan tapir with its curved trunk. *H. G. Rehb. f.*

SCOMBROKIA RUIONODORA KIMBALLIANA, *n. var.*

A fine inflorescence, with numerous branches and light purple flowers, was brought over by Mr. Godseff,

* *Maxillaria Hübschii*, *n. sp.*—Aff. *M. fucata*: pedunculo haud et distante vaginato; mento valde gutturosa; sepalis rotundatis; tepalibus ligulato rhombeis; labello rhombeo acuto transverso; callo depresso emarginato in disco; pilis strigosis non fractis in disco posteriori. *H. G. Rehb. f.*

† *Catasetum tapiriceps*, *n. sp.*—Multilorum, sepalis tepalibusque ligulatis acutis; labello conico saecato obtuso, margine libero subliter denticulato, marginibus lateralibus revolutis, margine antico obtuse retuso, carina transversa emarginata intus apposita; columna retro apicem apiculari bene evoluta deflexo, sotis infimis bene evolutis. Ex Brasiliæ imp. ch. Linden. *H. G. Rehb. f.*

Mr. F. Sander's assistant, from the grand collection of Mr. W. S. Kimball, Rochester, near New York. From the photographs kindly sent me by this gentleman, the riches of this mighty expansion of glass must be extraordinary. I was delighted to see the *Vanda cœrulea*, that cannot grow better in its native haunts (see *Gardeners' Chronicle*, 1888, fig. 8). Thus, it is satisfactory to have a wonderful *Scomburgkia* bearing Mr. W. S. Kimball's name. *H. G. Rehb. f.*

PHAEO-CALANTHE SEDENIANA, *n. hyb.*

Phaio-Calanthe irrorata, or, as it was originally called, *Phaius irroratus*, was raised from *Phaius grandifolius* crossed with the pollen of *Calanthe vestita*, and thus furnishes an example of a genuine bigeneric hybrid. The subject of the present note is another very interesting plant, though the parentage is slightly different from that of the first-named. Both were raised from *Phaius grandifolius*, but in the present instance the pollen was obtained from the hybrid *C. Veitchii*, so that three species of two distinct genera are concerned in the parentage. Both have the evergreen habit of *Phaius*; and it is a very interesting fact that an evergreen and a deciduous species have been successfully hybridised together. I am not certain that this has never been effected before, but Mr. Harry Veitch tells me that several similar crosses in other groups of plants have been attempted in the Chelsea establishment, though success has only been attained in the above-named instances. A fine inflorescence from Baron Schroder's magnificent collection has been sent to Kew by the Messrs. Veitch, the plant which produced it having been raised about six years ago by Mr. Seden. The flowers are large, with much of the general appearance of *Phaius*, though the lip shows a distinct approach to that of the *Calanthe*, while the bract also is very similar to that of the pollen-parent. The segments are of a pale delicate primrose tint, the basal portion flushed with pale rose, the lip pale primrose, bright yellow at the base and along the three keels, each of the three lobes conspicuously flushed with rose on their upper portions. The side lobes are large, and the front one very distinctly emarginate; it might be described as four-lobed, with two large side and two smaller front lobes. It has already been mentioned as *Phaius Sedenianus*, and as *Phaio-Calanthe* is a hybrid genus no confusion will arise by retaining the trivial name under which it is already known. It is an extremely interesting, and, to my taste, a decidedly pretty plant. It would be a most interesting experiment, and not unlikely give rise to some decidedly novel results, if Mr. Seden would give us some inverted crosses between these two genera, by making *Calanthe* the seed-parent. It would naturally be expected that in this way a deciduous *Phaio-Calanthe* might be produced. *R. A. Rolfe.*

TYING AND TRAINING PLANTS.

WINTER is the best as well as the most convenient season for training and tying most kinds of indoor plants, a few remarks on the subject may therefore not be out of place. Those who are old enough to remember the way in which pot plants at one time were grown will not require to be told what was their general appearance. Little or no thought was given to the form which the plants naturally assumed, or to the desirability of attempting to cultivate them in a way that would convey some idea of their true character. Glass was dear, and steam-power had not come into use in preparing the timber needed for the construction of horticultural buildings, consequently these erections were costly, only the wealthy indulged in them, and to a limited extent only. The aim was directed more to the possession of a large number of kinds than to any attempt at superior cultivation. In the early stages of a plant's existence stopping the shoots with a view to the formation of a bush-like habit, was little practised; in fact, with the limited glass accommodation which gardeners then had at command, it would not have answered to

treat plants in a way that would make them occupy much room. The re-pottings were few and far between, comparatively little root-room being allowed, which, combined with the prevalent idea that pot plants, especially the slow-growing, hardest wooded kinds, would not bear manurial stimulants, resulted in the growth being weak and puny. This was further aggravated by the way in which the plants were crowded together, far from the glass, in the dark badly constructed houses that plant growers of the past were compelled to make shift with, and which, even at the present day, when their bad influence is better understood, are much more common than they should be. As a matter of fact, all that could be said for pot plants in the condition they were generally met with was that they were interesting more or less from their being indigenous to countries where the climatic conditions differ widely from ours.

Cheap glass and a better acquaintance with the requirements of the numerous plants that are kept wholly or the greater part of the year in glass-houses, brought about a disposition on the part of gardeners to grow them in a way that would give some idea of the habit and character of the plants they cultivated, and of their flowering capabilities. Yet it is only just to say that the pioneers, who inaugurated a better system of cultivation, did not wait for the advent of cheap glass, and well constructed houses, but set to work with the indifferent structures they had at command, and thus led the way that has since been followed with more or less success by all who aspire to do something better than reproduce the pot grown starvelings that used to fill our plant-houses. The greater portion of the plants that are subjected to pot culture, that have not a climbing habit of growth, are naturally of a dwarf bushy character, many of them being to some extent procumbent, that is, with their lower branches usually resting partially on the ground in the way of our native Heaths. When plants of this description are grown under glass, no matter how skilfully they are treated, and how well constructed and light the houses may be, the branches will be longer jointed and somewhat weaker; hence, with many, the necessity for some support in the shape of sticks and ties. But in this the object of the grower should be to shape his course so that no more will be required than the natural habit of the plant renders necessary, for at best supports of any kind are only necessary evils. Plants that are naturally of a bushy habit, when naked at the bottom are intolerable in the eyes of the grower who aims at a high standard of cultivation. To avoid this and reduce the need for much tying, when the specimens get large, it is requisite to attend to the traioing during the early stages of the plant's existence by timely stopping the shoots so as to get the future specimen well furnished with branches at the base. Where this is neglected too many sticks are required after the plants have acquired size. In addition to stopping, whilst they are quite young, the strongest shoots should be brought down to the rims of the pots and there secured, leaving the weaker ones in a more or less erect position, by which means they will gain strength, so that the growth collectively will be more equal. Where the reverse of this course is taken, it naturally follows that the strongest branches so far take the lead that the weaker ones, which are less favourably placed for getting their share of the sap, are rendered still weaker: the outcome being, that the latter perish, leaving the specimen naked at the bottom—a condition found in half the plants one meets with before they get old.

This timely training applies to plants of all kinds, from a Pelargonium to a Heath or New Holland shrub. It does not require a very intimate acquaintance with the plants that are usually grown in pots to enable anyone to see that there is a wide difference in the amount of support needed by different species, not only whilst they are young, but equally so when they get large. When only required for ordinary purposes such things as Azaleas, Epacris, or Gardenias, and others of a like character, require little in the way of sticks or ties; whilst weak-

wooded species, such as *Dracophyllum gracile*, *Aphelexis*, *Chorozeamas*, *Boronias*, most of the *Ericas*, and many others, cannot possibly be grown without sticks, however well their early training has been attended to. Plants like these, the branches of which are naturally too weak to maintain erect or partly erect habit, not only need assistance to keep them in shape whilst they are young, but the larger they get the more they require in this way. The shape that plants are trained in has to do with their continuing to maintain a healthy vigorous condition from the bottom upwards than is often taken into account. Unless a plant is broader at the base than above, the lower branches are sure to get weak, and ultimately perish for want of the necessary light, which those above prevent their getting.

Nothing is more objectionable than to see a collection of specimen plants of various kinds resembling each other so much that they might all have been cast in one and the same mould. The pyramidal shape, somewhat rounded, and not too much pointed, answers best for many things, varying the form so that some are equal in diameter at the bottom to that of their height, whilst others are more erect. The rounded bush-shape suits most of the *Ericas*, and others of a like character of growth. In all cases a plant of this description should be furnished with shoots and healthy foliage down to the rim of the pot; without this it is defective.

STAKING AND TYING.

The way in which this is often done, especially with plants that require a good deal of support, would lead to the supposition that those who carried out the work forgot that there were roots in the soil, or else had an idea that it did not matter to what extent they were bruised and broken. It is a common thing to see such of the plants above named as need a good deal of support, with numbers of sticks stuck deep in the ball, the insertion of which, in the way the work was done could not fail to have injured many of the roots. I feel convinced that to this cause the death or unhealthy condition of many valuable plants is directly traceable, though it often happens that the effects may not be apparent soon enough after the staking has been carried out to rouse suspicion as to the cause. This may easily be avoided if only a little forethought be brought to bear on the matter. When shifting hard-wooded plants that require more or fewer sticks into larger pots, the additional new soil round the ball is unoccupied by roots: this gives a chance for re-tying. As soon as the potting is completed, if the sticks necessary to support the outer branches are put in, no injury can be done. This is the practice I have always followed, being careful, when re-tying was required to put the new sticks into the holes which the old ones have occupied. To make sure of this, in place of taking the old sticks out in the usual manner when a plant requires re-tying, I cut them off an inch or two above the soil with a strong pair of *secateurs*; in this way each stump can be drawn out as the work proceeds, to make way for the new stick.

As already said, there is a wide difference in the amount of support which some plants require as compared with others. And the purpose for which the plants are wanted makes a still greater difference. When only intended to stand in greenhouses and conservatories comparatively few sticks are needed or should be used, as anything in the way of stiff training is highly objectionable, and quite unnecessary. The tops of the shoots should be left loose, so as to hang in the natural position. A skilful hand will tie plants in this way, so that the sticks and ties are scarcely perceptible; in fact, a good many things which, like *Azaleas*, form branches strong enough to hold their position when the plants have not to be moved far when in bloom, require no support at all further than perhaps a single stick to the leading stem. When plants are required for exhibition, and consequently have to be conveyed a greater or less distance, the case is very different, as many a young hand at showing has discovered to his sore disappointment; for unless all the shoots are secured

so that they cannot thrash or rub each other, the flowers chafe so as to be completely spoiled. The tying which is thus indispensable gives the plants a more or less stiff formal appearance, and has caused a good deal of meaningless criticism, for if flowering plants of the character in question are to be exhibited at all they must be tied, so that the flowers will not get injured. *T. Baines.*

PLANT DISEASES.

FINGER-AND-TOE.—Dr. J. Brunchorst,* of Bergen, states that the best way of coping with the disease of Cabbages, Turnips, &c., known as Fingers-and-Toes, is to turn the seed as frequently as possible; but he has also found that in the case of certain more valuable sorts, which have to be carefully raised in frames, and which are very apt to be attacked by the slime-fungus, *Plasmodiophora Brassicae*, which causes the worst form of Fingers-and-Toes, it is possible to prevent the ravages of the parasite by other means.

The seedlings of these plants are infected while still in the soil of the hotbed frames, and in some cases only 10 per cent. of the plants survive. In a certain garden planted with Cabbages, he observed that whereas the majority of the plants were badly infested, there was one strip in which a much greater percentage of the plants were healthy; the plants and the soil were the same all over. It turned out that the seedlings which gave rise to the plants in this strip were from a portion of seed which had remained over from the sowing in the hotbed frames, and which had been in a box separately. No Cabbages had been raised in this box before, as they had been year after year in the frames. The explanation was simply that the soil in the box in which the seedlings were raised contained no fungus.

Experiments showed that it is possible to disinfect the bad soil. Two clean boxes were taken, holes bored in the bottom, and the boxes sunk in the badly infected soil of the frames, and the boxes then filled with the infected soil. By means of a rod, the experimenter then bored six deep holes in the soil of each box; one in the centre of the box, and five others in a circle round it. Into each hole were placed 50 grains of carbon-bisulphide, the holes filled with soil, and the disinfected boxes left for a week in order that the carbon-bisulphide might diffuse in the soil, and the surplus evaporate. Cabbage seed was then sown both in the two disinfected boxes and in the soil immediately around—the latter was the same as the soil in the boxes, but not disinfected.

After two months he lifted the plants, and found that while only 2 per cent. of the plants from the boxes were attacked by *Plasmodiophora*, at least 80 per cent. of the plants from the soil outside were infected with that fungus, and badly affected with Fingers-and-Toes. *M. B.*

THE ROT IN GRAVES.

Dr. L. Savastano, in studying this disease, has proved the presence of a special bacterium. He has cultivated this organism, and has reproduced the disease in all its characters by inoculation, and thus concludes that the bacteria are the direct cause of the malady. In the yellow spots and even in the leaves the experimenter has found the same bacteria. Inoculation made in the bunches gave results comparable to the preceding. These two bacteria may be, according to the Doctor, considered as the same organism, producing different effects according to the medium in which it develops.

EXPERIMENTS ON THE PARASITISM OF *AGARICUS MELLEUS*, VAHL.

The opinions of pathologists differ greatly on this question. Some maintain that the *Agaricus* is a mortal enemy of the host-plant, being able to attack it while in good health and to kill it; others deny it this power, and declare that it has not the strength to attack a healthy plant, but only one already

* *Bergens Museums Aarsberetning*, 1880, pp. 2.9—231.

weakened; it can only give the finishing touch. Dr. L. Savastano arranged that the battle between the parasite and its host should be fought out. He planted or sowed plants which are commonly attacked by the parasite—some in pots, some in the open ground, into which were plunged pieces of wood containing the spawn of the fungus. The experiment was conducted with thirty-nine different plants belonging to fourteen species (Peach, Walnut, Olive, Fig, Chestnut, Plums, Vines), and continued for two years. During the periods of infection and reproduction the plants grew normally, and were not injured by the fungus. Dr. Savastano therefore thinks it proved that the parasite is unable to attack young and healthy plants.

WOUNDS AND GUMMING.

Dr. Savastano has previously ascertained, in a study of the phenomena of gumming in *Amygdalaceæ*, *Aurantiaceæ*, &c., that in his country (South Italy) a wound to the plant almost always causes a proportionate amount of gumming. M. Carrière denied the accuracy of this observation as regards Peaches round Paris. Dr. Savastano states that he has been experimenting, and finds that a plant is more liable to gum in the south of its cultural area than in the north, and that this way the discrepancy between M. Carrière and himself may be explained.

THE RECONSTITUTION OF THE ROYAL HORTICULTURAL SOCIETY.

If to serve and suffer for a society qualifies one to write or speak of its affairs, such a privilege will probably be granted to myself as the only practical gardener in the United Kingdom who won and lost a Forty Guinea Life Fellowship through my efforts to popularise its institutions and extend its usefulness. Believing for years that most of the evils that fettered its freedom and curtailed its influence arose from the giving to metropolitan centres and interests what was meant for the horticulture and horticulturists of the United Kingdom, I had the honour and privilege some twenty years ago of helping to launch the Society on its provincial campaign, the main objects of which were the endowment of the old Society with new resources and wider capacities of service, its reconstitution on a wider and a more popular basis, and the general stimulation of national horticulture. The new start towards renewed prosperity and enlarged usefulness proved most propitious. The first provincial show of the Royal Horticultural Society, held abreast of the Royal Agricultural Society of England at Bury St. Edmunds in 1876, proved a brilliant success alike financially and horticulturally. But somehow or another the metropolitan and local elements of the Society seemed to paralyse the energy of its provincial enterprise, and hence, after a few timid, cold, mistrustful advances, provincial horticulture was tossed aside, and the Society took to lawn tennis to keep her going. It will not help the Society out of its present difficulties to discount all these difficulties as over and done with, having little or no bearing on the present circumstances. The exact contrary of this is true. Now, as then, success or failure turns on the previous question—of its localism or its nationalism. If the former, it is doomed to fail, as it has done in the past, though it has had the advantage of three very potent local centres—Regent Street, Chiswick and South Kensington. If the latter, it is bound to succeed, for a horticultural society, truly national in name and aim, must embrace the nation.

AFFILIATION OF LOCAL SOCIETIES.

The system of affiliation strongly advocated by many of us many years ago has been fairly successful. But the very loose tie of affiliation needs tightening into something akin to amalgamation in the government, work, honour, of a national society. By such gradual evolution from localism into nationalism the Royal Horticultural Society might yet aspire to lead the horticultural enterprise,

science, and practice of the nation on to conquests and yet higher achievements.

A NEW CONSTITUTION.

To this end, however, it must be endowed with a more popular constitution, establish a perfect equality of *status* and privilege among its Fellows, secure freedom of action, and from encumbrance obtain and maintain thorough independence, and cherish lofty views of service and of duty to the nation at large. The very first step necessary in pursuit of these objects is a lowering of the franchise, or a reduction of the terms of Fellowship; for a national horticultural society with the rank and file left out is a misnomer, if not an absolute mockery. Neither need the Society lose in prestige, power, usefulness, through a lower money-rate of Fellowship. Then talent might surely be allowed to purchase Fellowship as well as money. It does so to some extent now, only Fellowships so granted are denuded of all powers of government, as if the Society were actually afraid of the ability of its few honorary Fellows. What more honourable reward for unusual cultural, botanical, decorative, or literary merit, or for extraordinary excellence in the designing, furnishing, and management of garden and landscape than the Fellowship of a truly national horticultural society?—such Fellowship to be equal, as a matter of course, in honour, privilege, and voting or governing power to purchased Fellowships. A truly national Horticultural Society should know of no inequalities among its Fellows. It needs hardly be added that a national horticultural society must be governed by its peers, that is, by horticulturists. Having placed the right men in the right place by careful selection of duly qualified and discreet Fellows, we must safeguard the Society against the most frequent source of bad government hidden beneath the plausible phrase and practice, "eligibility of re-election." In practice this really means government in perpetuity by the same set of Fellows or their nominees. That frequent change and constant accession of fresh blood, which is as essential to the robust health and youthful vigour of societies as of individuals, might readily be ensured by insisting that one-third of the Council should absolutely retire annually, none of such retiring members to be eligible for re-election till after three years. The simplest possible means should also be devised for the nomination and election of Councilors, so as to keep the governing body in close touch and complete accord with the wants and wishes of the Society. No society can prosper with a Council in antagonism with itself, nor in ignorance of the wants and wishes of its constituents; and the secret of all good government, alike in the State and societies learned or unlearned, is to keep the executive power in harmony with the representative. In pursuit of this vitally important end, and as the shortest cut towards it, it might be needful to adopt voting by proxy, as it is difficult to see how otherwise anything like an equality of voting privileges and powers could be established among Fellows, some of whom could impress their will on the policy of the Society by a walk of a few yards, while others to do likewise might have to journey 50, 100, 200, or 500 miles.

A GARDEN OR NO GARDEN.

Considerable difficulties will doubtless be encountered in reconstructing the old Society, or forming a new one on a truly broad and national basis. On the very threshold the knotty question of garden or no garden would have to be grappled with and settled. It would be presumption in me to attempt to determine such a weighty matter. No one can, however, fail to see that for societies gardens, either for experiment or illustration or as a nucleus for distribution, are less needed now than when the gardens at Chiswick were established. Commercial horticulture especially, to say nothing of private gardening, has advanced so rapidly, that a national horticultural society, endowed with unlimited resources, would have great difficulty in running abreast with it, either in selection, cultivation, or results. Besides, the Government do a good deal for botany at Kew, Edinburgh, and Glasnevin, and as

much as can well be done for decorative gardening in the London parks; while municipal and other public bodies, learned societies, and private gentlemen vie with each other in the formation of parks and pleasure grounds, and the girthing of our towns with sanitary cordons of verdure and beauty. True, we have no horticultural or experimental garden excepting Chiswick and it would be in some sort a national misfortune to lose it. But that surely need not follow. Should the Horticultural Society prove unwilling or unable to sustain it, the Government might step in and find the money, and keep it a going concern worthy of our national renown, or its fruit and vegetable treasures might be engrafted on to Kew just as ample space is reserved at Versailles for the utilities of horticulture in close proximity to the almost bewildering profusion of its artificial and natural embellishments. But this is rather anticipating. The chief objections to the possession of a garden by a national horticultural society are the cost and the tie—the latter perhaps proving the greater hindrance to truly national work.

In this connection it is impossible to ignore the fact that the Royal Agricultural Society of England has virtually revolutionised our national agriculture without either hiring or owning an acre of land, either for experiment or illustration. It has been the great teaching authority, and its other two mightiest stimulating forces have lain in its discovery and certification of merit. In the early history of the Royal Horticultural Society it attempted little more than this. So far I agree with Sir Joseph Hooker in the *Gardeners' Chronicle* of January 7, that something like a revival of its old home and functions in London, with a central heart to move and a head to guide and advise might prove a long step forwards as well as backwards in the history and policy of the Society.

PUBLICATIONS.

In any case, a local habitation and name in such a central place as the metropolis will be essential as a convenient *rendezvous* for horticulturists; a home for the Lindley Library and other literary and art treasures; meetings of Scientific and other committees, exhibitions of rarities, novelties, and horticultural or botanical subjects of exceptional merit, &c. Subordinate to the question of garden or no garden would naturally follow that of Journal or no Journal. There will doubtless be a general consensus of opinion among horticulturists that there must either be no Journal, or that alike in get-up and internal quality it must furnish the highest possible example of the literature of horticulture—cost what it may for contributions or editorship. Our societies are now so fully and faithfully reported and so well served by our Press that mere records of their proceedings in special journals have become unnecessary and superfluous. Still, it is an open question whether a horticultural Quarterly, somewhat on the high educational and literary lines of the *Journal* of the Royal Agricultural Society of England, might not create a large field of usefulness for itself, and prove a source of power as well as of profit to a truly national horticultural society.

THE DUTIES OF THE SOCIETY TO THE STATE.

Such a society might also patronise literature in other forms—such as, for example, by issuing or offering prizes for essays on semi-horticultural subjects, as, for instance, the importance of making horticulture a recognised branch of our national education, and its introduction into the curriculum of our parochial, board, boarding, commercial, middle-class and other schools and colleges; the sanitary and pecuniary importance of having gardens attached to dwelling-houses: fruit and vegetables as food; the reclamation of waste and Crown lands and their devotion to horticultural use, the allotment system in its social, moral, and material bearings; plants and flowers in the home, and shrubs and trees in towns; the preservation of open spaces, waste products in relation to horticulture, foreign climates and products, national and international exhibitions and their effects on horticulture and the peace and prosperity of nations, &c. The chief mission of a truly national society would be stimulatory, the collection, distribution, exhibition and certification of merit over the widest possible area—all its work at home and abroad—should be national in its scope, character, and objects, and in harmony with the wants of the times.

EXHIBITIONS AND MEETINGS.

One or more great shows a year should be held in the provinces, and probably also one great and as many little ones as seemed good in London. Conferences, Congresses should be held, and popular lectures with telling expositions and illustrations given at these shows on the science and practice of horticulture. Prizes might also be offered for the best gardens in the districts visited—design, furnishing, keeping, culture, products, and cost relatively to size—all to have due consideration in determining the awards. Possibly, too, it might be possible to establish Educational and Literary in addition to the Fruit, Floral, and Scientific Committees, and for these to test and certify the merits of thinkers and workers in other fields than fruit and flower growing. As to the privileges of Fellows, Fellows' tickets should admit to all the meetings of the Society, confer the right of nominating and voting for all the members of the Council and committees, and ensure a copy of all the Society's rules and publications.

STATE AID.

Some contend that the Government ought to find the ways and means, and also provide Professors for teaching horticulture at the Universities. It has been said, and with reason, that there might be a Board of Horticulture, as there is a Board of Trade and of Works, such board to include Agriculture and Arboriculture as branches of horticulture, and that to such Board might be relegated the formation and working of a national horticultural society. Well, all this may come, but I am somewhat sceptical of the benefits of Government departments. We had a taste of it once and did not like it, and the Government of the day, when Mr. Ayrton ventured to assume the functions of State gardener, aroused such a hornets' nest as to sting him and his colleagues out of office. Besides, where is the benefit of having done for us what we can probably do much better for ourselves? Nor can there be any question about the ability and power of horticulturists with easier terms of Fellowship to establish and support such a society as shall be a credit to us and furnish one more striking example of British self-help to other lands. Self-government and self-support are, after all, the highest forms of life—horticultural or other, and in the end these generally prove the most successful as well as durable. *D. T. Fish, an ex-Life Fellow of the Royal Horticultural Society.*

NURSERY NOTES.

TREE PEONIES AT MR. WARE'S NURSERY.

This beautiful group of hardy Japanese shrubs is now receiving more attention from growers than was formerly done. The re-introduction of these plants has been welcomed by Mr. Bateman, of Worthing, and other admirers of Tree Peonies; the former gentleman, who some years ago used to grow them extensively, endeavoured greatly to get them to become popular. There is no doubt but that their re-introduction is mainly due to Mr. T. S. Ware, of Tottenham, whose display of these magnificent flowers was always a great feature, and one which was much appreciated during the last few years. The improvement made on the old *P. moutan* and other sorts like *Banksi*, *papaveracea*, &c., is worthy of notice, some of the huge double blooms being 24 inches in circumference, and including a great range of colour, from the purest white to the most brilliant scarlet and the deepest purple-violet. It is the opinion of good judges that the white and delicate pink forms are the most attractive, while some of the dark rich purple varieties have the additional merit of being deliciously fragrant. They have proved to be quite hardy in milder parts of the country, especially the European garden forms, but as a rule they do best in a sheltered position facing the south or west, thriving in any good deep soil when it is enriched with decayed manure. As regards their employment in gardens, they can be advantageously used between low growing shrubs, in the mixed border, or as single specimens on the lawn. The best time for planting is undoubtedly in autumn, as they form a quantity of white fibrous roots during the autumn and winter

months. If good plants are planted they will produce quantities of flower the second and third year after planting. They may also be grown in large pots for greenhouse and conservatory decoration, and I do not know anything to equal them when in full flower; of course they will then flower a month or so earlier, and are better kept in a cool house after the flowers are fully expanded.

To assist those who desire to form a collection of these I will enumerate a few of the choicer sorts which flowered last year:—*Athlete*, large double flowers of a delicate lilac-rose, with guard petals of a rich dark maroon; *Bijou de Chusan*, a lovely Chinese variety with large delicate rosy-white flowers: the centre petals are loosely folded, and glisten like crumpled satin; *Carolina*, full double flowers of a lovely nankeen-flesh colour; *Fragrans maxima*, pl., a large double flower of a coral-pink, edged with rose-salmon, and very sweet-scented; *Lactea*—this is the best variety I have seen, well-established plants produce gigantic blooms, fully 8 inches in diameter; *Lord Macartney*, a Chinese variety with brilliant cherry-carmine flowers; *Louise Mouchelet*, nice globular flowers of a delicate flesh-pink, with a fine satiny lustre; *Osiris*, another charming Chinese form of a rich deep salmon-pink, and is sweetly scented; *Reine Elizabeth*, large double flowers of a rich deep salmon, shading to pink towards the margin; *Zenobia*, semi-double flowers of a dark purplish-violet with a beautiful bluish metallic lustre. *C. S.*

KEW NURSERY, RICHMOND, SURREY.

This nursery will probably be best remembered as having been once in the possession of Mr. Herbst, and when under his proprietorship it was well noted for market Palms, Lily of the Valley, &c.

A peep into a market-plant nursery of any note usually gives us a pretty good insight into what may be called the "commercial side" of horticulture. We see therein quantity combined with good quality—a combination unfortunately not always to be met with in these hurrying times. The nursery is now occupied by Mr. K. Drost. One of the features at the time of my visit was a great number of forced English Lilac in splendid condition. It was of the nature of a pleasant revelation to see a house of Lilac, the plants filling it from end to end, many examples being 5 to 6 feet in height, and crowned with their snow-white blossoms. Glancing along the tops of the plants gave one the idea of a veritable snow-field!—and the perfume emitted from such a number of plants I must leave the reader to imagine. Mr. Drost has been cutting for market since October last, and will continue to do so for some time yet—indeed, he assured the writer that last year he cut a month after the Lilac had done flowering outdoors.

Hitherto we have depended upon the French for our Lilac supply, but Mr. Drost has now for the third year very successfully demonstrated that we can produce Lilac of equal quality. It may be remarked that the individual flowers are about the same size as the French Lilac, but the spikes are larger, and are said to "travel" better than the French.

Of Lily of the Valley we noted a fine batch in flower; single and double-flowered Tulips, in the most popular varieties, in quantity. These, with the Lily of the Valley, have furnished a good market supply for some time. The useful old double-flowered white *Primula*, with its charming rosettes of flowers, is much grown here, the flowers and plants finding ready sale in the market.

A good thing may be noted in *Viburnum Opulus* Snowball, with handsome globular heads of flower, forming a charming decorative subject when cut, as distributed from here, in shoots of 5 or 6 feet in length.

By way of conclusion, a few words on the Palms and other foliage plants. Some idea of the extent of the trade done in Palms may be gleaned from the fact that about 55,000 are grown, to be seen in all stages of growth, from innumerable dots in 60's to the shapely and well-foliated specimens for furnish-

ing purposes. In such a nursery of course only the most popular kinds are grown, a list is therefore totally unnecessary. The *Kentias* are found to stand best for general furnishing purposes, while one of the hardiest is *Latania borbonica*. We observed a wonderfully fine lot of that best of table Palms, the graceful *Cocos Weddelliana*.

Of Ferns a good and select collection is grown, the now well-known and beautiful *Pteris cretica* *Mayi* being remarkably well done. *B.*

MR. B. S. WILLIAMS.

Time was when Upper Holloway, and the Archway at the foot of Highgate Hill, were a full day's outing for the citizen; but now houses line the whole way from Islington, and fog plays sad havoc with flower and foliage, causing the utter loss of the former, and besmirching the latter. Blacks are so thick in the air in that neighbourhood, and stick to the roofs of the glass houses so pertinaciously, that nothing less than scrubbing with a brush will remove them. This is an additional expense, a roof-washer, who does but little else, being a necessity of successful plant growing there.

Being in search mainly of flowers that open during the winter months, the inspection extended to the greater number of the houses. In the lean-to house at the end farthest from the high road there were found in full bloom several plants 3 feet or more in height of the double-flowered *Sparmannia africana*. Every one knows the old favourite inmate of the greenhouse, which almost every one possessed, but none grew into a nice-looking plant. This double form, with its corymbs of full rosette-like blooms, is much handsomer than the single ones, and its rosettes with the purple anthers inserted among the centre petals, will be much admired either on or off the plant.

In an intermediate temperature plants in flower of *Tabernaemontana coronaria flore pleno*, and *T. canassii*, were observed. These are such charming pure white perfumed flowers, that they should never be absent from collections of warm-house plants. They are preferred by many to whom the scent of the *Gardenia* is unpleasant. In the same house plants of *Toxicophlax spectabilis* were opening their spikes of white blossoms. Of *Cyclamen* a very good strain were in full flower, as was also a fine large specimen, such as is rarely seen, of *Daphne indica alba*. This was a specimen which had never been spoiled by the use of the knife, either in pruning, which *Daphnes* dislike, or that minor form of it consisting in snipping off the flowers; and as a consequence it was crowded with flowering wood and ample foliage.

In the fernery one of the most conspicuous plants is *Adiantum Williamsi*, the fronds of light fresh green showing up distinctly amongst the more or less rusty-looking ones of other varieties and species. The habit is like that of *A. scutum*, but is still more open and slender.

In the Orchid-houses a number of species were observed in bloom, but there were few that had not suffered loss of flowers during the days of fog in January. *Oncidium sarcoodes* was coming into flower in quantity: the rich brown flowers of this species are very ornamental; *O. macranthum*, an autumn flowerer, had been pushed on in strong heat, and was just opening its buds. Some few *Calanthe* blooms still remained on the plants; the white and lilac *Miltonia Kramerii*; *Dendrobium heterocarpon*, whose pale yellow flowers, densely packed on the pseudobulbs, were unaffected by fog; and *Epidendrum ciliare*, were each objects to admire; presently they will be put in the shade by the *Cattleya Triane*, *C. Mossii*, *Acrides*, and other gorgeous species, of which only the sheaths of bloom and raceme spikes are yet visible. It is a pity growers so much neglect the species of *Acrides*, seeing how much grace and beauty are found in their flowers. We think that other East Indian Orchids are under a cloud just now, and ought to be more prominently brought out at exhibitions. A large specimen of *Cymbidium Lowianum* was throwing up strong

flower-spikes, and another of the Chatsworth variety of *Colognye cristata* was loaded with its handsome flowers; and *C. pandurata*, the species with green and black flowers, was observed in large examples.

The *Vanilas* in the house we are now in are a wonderfully healthy lot, feathered with leaves down to the pot; and *Calanthe veratrifolia* was more healthy-looking than we are accustomed to see it. The plant gets, as a rule, too much heat at all seasons, hence its comparative scarcity. It was a disappointment to discover not a flower on *Phalenopsis Schilleriana*: all open flowers had been swept off by fog. A big specimen of *Cymbidium eburneum*, with twenty-seven flower-spikes, will be worth seeing when in flower. Many species and hybrids of *Cypripediums* were bearing open flowers, amongst them being *C. Dautheri*, *C. macrochilum*, *C. porphyreum*, *C. nitens*, *C. Amesianum* (a hybrid to be sent out this year), *C. Morgania*, *C. Dayanum*, and *C. politum*.

A few plants of *Odontoglossum crispum* rewarded a peep into their compartment.

THE ALGERIAN FIR.*

ABIES NUMIDICA.—It seems strange to those of this generation who have the opportunity of comparing the living plants in cultivation that this Fir should ever have been confounded with the Spanish Fir, *A. Pinsapo*. It is really nearer to the common Silver Fir, *A. pectinata*. The surprise will, however, be transient to those who remember, on the one hand, the imperfect materials and defective information which botanists commonly have when they are first called on to describe a species, and, on the other, the remarkable variations exhibited by these plants, sometimes even in the same plant at different stages of growth. The name here adopted is the one most in accordance with accepted views as to the allocation and affinities of the species.

The tree in question was first discovered by Captain De Gibert, in 1861, in the mountains of Babor, at an elevation of from 4000—6000 feet, intermixed with the Atlas Cedar, on limestone soil, and was mentioned by Cosson as *A. Pinsapo* var. *baborensis*. M. de Lannoy also found the plant in the province of Constantine, sent specimens in 1862 and in 1864 to the Jardin des Plantes, which M. Carrière described in the *Revue Horticole* as *A. numidica*.

It is not necessary in this place to give a full botanical description of the tree such as may be found in the books which have treated of this species. It may suffice to add a few particulars observed in the cultivated plants at Pampisford, Kew, and elsewhere.

It forms a handsome pyramidal tree, with the habit of *Pinsapo* or *cilicica*, rather than of the common Silver. The young bark is cinnamon-brown, glabrous. The leaves come off on all sides but are twisted so as to lie in one plane, densely set, very deep green, flat, linear oblong, sometimes emarginate, sometimes pointed; those on the sterile branches generally rounded, but slightly pointed at the apex on the fertile branches. There are about eight rows of stomata on either side of the midrib beneath, and a few near the tip on the upper surface. A transverse section of a leaf (see fig. 23, p. 141), shows a double layer of hypoderm cells which give rigidity to the leaves, then two layers of deep green palisade-cells, in which the work of the leaf is mainly done. Then comes the ground-tissue of the leaf, through the centre of which runs the vascular bundle, of a kidney-shaped form, with the concavity upwards. The bundle-sheath and pericycle are well defined, and the xylem or woody portion divided into two wedge-shaped masses, converging towards the upper surface. The resin-canals

are placed in contact with or just above the epidermis on the underside, not free in the ground tissue, as generally in *Pinsapo* (fig. 22). The leaf-buds are ovoid-acute, resinous, brown, the constituent scales oblong-ovate acute, cartilaginous, the upper ones larger and more membranous. When the shoot commences to grow it bursts through the lower scales, which form a kind of sheath or tube longer than in most of its allies, while some of the thinner scales are torn at the base by the force of the growing shoot, and lifted up on its extremity in the form of a small cap. During active growth the shoot curves downwards (epinastic), owing to more rapid growth on the upper as contrasted with that on the lower surface. The male flowers of the cultivated plant we have not seen, but we are glad to have the opportunity—thanks to Mr. Nicholson—of figuring the cone (fig. 23), which he obtained from the courteous and energetic M. Pavart, the superintendent of the State Nurseries at Trianon, Versailles. The figure shows better than words can do what the cone is like. In colour it was of a dull brown, the bracts projecting beyond the scales (not concealed within them, as in *A. Pinsapo*). It is worth notice that in the Algerian specimens in the Kew herbarium the bracts are shorter than the scales, though otherwise quite like those of the cultivated plant. The relative length of bract and scale is known to vary in other species of the genus, and can therefore not be relied on as a distinctive character. Each bract has an oblong ribbon-like stalk dilated above into a spatulate limb, generally more indented at the edges than shown in those represented and prolonged into a long slender acumen. The seed-scales are brown, covered outside near the tip with felted down, obovate or rounded at the top, wedge-shaped at the base where they are inseparable from the bract. The seeds, are obliquely obovate of a rich, deep glossy brown colour, and surmounted by an oblong retuse membranous wing of a curious tint of drab.

FIG. 22.—*ABIES PINSAPO*.

Leaf section from nature, showing resin canals free in the substance of the leaf.

There was a good deal of controversy when the plant was first made known as to what name it should bear and as to whether it was to be considered a distinct species, or a variety of the Spanish *Pinsapo*. M. Carrière's last word is that there are two forms in Algeria—one the *A. numidica*, here described; the other truly a variety of *Pinsapo*, which is the *A. Pinsapo* *baborensis* of Cosson. Our own impression, from the study of herbarium and cultivated specimens, is that there is but one species, and that one not *Pinsapo*. The appearance of herbarium specimens is, however, very often very different from that of the plant in the fresh state, thus the cylindrical leaves of the living *Pinsapo* spreading on all sides are in some cases hardly recognisable in the shrunken flattened leaves of the dried specimen.

Of late years the anatomical structure of the leaf has been employed to discriminate between different species, but this character, like most others, is not free from variation. Thus, while Bertrand finds the resin canals of *A. Pinsapo* free in the tissue of the leaf (parenchymatous), McNab figures them as in contact with the lower epidermis. Our own preparations from undoubted *Pinsapo* are mostly in accord with the observations of Bertrand (see fig. 22), but our preparations show some variations in this particular. In *numidica* Bertrand and McNab described the resin canals as in contact with the epidermis, and so we also find them to be.

In Algerian specimens the old bark is ash-grey, the young rind orange, glabrous; the leaf chatrices are very densely set, circular, depressed. The leaves are in one plane, the uppermost shorter than those beneath, linear oblong obtuse, deeply channelled in the middle above, and with stomata in the

groove; margins reflexed, midrib very prominent beneath. Bud ovoid, conic, scales not resinous, oblong-lanceolate, persistent, forming an unusually well-marked sheath at the base. In *Pinsapo* the scales are rounder, shorter, and more resinous, and the leaves under no circumstances have such a deep narrow furrow in the centre. The variation in the relative length of the bract and the seed-scale has already been alluded to.

As an ornamental tree, *Abies numidica* may be highly commended for its shapeliness, its bright cheerful foliage, and unassailed hardihood. On this latter point Mr. Nicholson has favoured us with the following details:—The tree from which the cone here figured was taken was planted in the park at Trianon about 1859, having been raised from seed a few years previously. Its height is now about 25 feet and as it survived 29° C.—that is, say, 20° below zero of Fahr., or 52° Fahr. of frost—in 1879, its hardihood had a pretty good test. In the same year numerous fine trees, including some originally introduced by Michaux, were destroyed. The species is, however, reported to have been injured in 1879—80 at Zurich and at Orleans, where the tree was subjected for three weeks to a temperature of —18° to 25° C. (zero to —13° Fabr.), and on one occasion to —18° Fahr.

Turning to the elaborate Frost Report published under the auspices of the Scientific Committee, by Rev. G. Henslow, we find that it was uninjured at Clitheroe, in the West Riding of Yorkshire, where the temperature went down to 12° Fahr. and 9° Fahr. respectively in the near neighbourhood. It was slightly injured at Pampisford, Cambridgeshire, by a temperature of 1° Fahr. At Coombe Wood, Surrey, according to Veitch's *Manual*, it was not injured in the least, although the temperature at Wimbledon (close by) was recorded as low as 11°.

FERTILISING MOSS.

At the risk of being charged with plagiarism we beg leave to repeat what we wrote just a year ago with regard to this interesting subject. We do so because what we then urged has been so amply verified during the past year by your correspondent, Mr. Roberts, and others, that a little repetition may incite and encourage further investigation in the direction indicated. We do not wish it to be inferred that the improvement we have introduced on the old-fashioned plan of packing small bedding plants in balls of moss where pots or room, or both, were scarce, is anything more than an innovation brought about by intelligent research, assisted a little, perhaps, by scientific knowledge, but certainly much more by necessity—the mother of invention.

The broad problem that plants could be manufactured, by using the self-contained elements in the seeds was solved by the eminent chemist, M. Ville. Having provided a simple means of supporting the roots of plants in an element containing no fertilising properties—pure silica—he proceeded by the use of distilled water to germinate seeds of grain; succeeded, that is, in producing in the first instance from seeds weighing 15 grains, a crop weighing about 90 grains by the help of air and water alone. His future experiments when adding the soluble plant foods in the various forms to the distilled water were much more successful. His conclusions amount to this: that complete development of plant life can be brought about by using a few chemical products of definite purity, some distilled water, and a few seeds, the result being a crop that will in every respect bear comparison with those obtained from good soil.

The principle being established, that calcic-phosphate, potash, lime, and nitrogenous material are the elements requisite to form a perfect natural soil, it is not difficult to vary the proposition by ascertaining what elements, combined with a given medium, are necessary to promote plant life apart from soil altogether. In the case in question, that of fertilising moss—this is simply a question of experiments. Basing these experiments on the knowledge that all mosses contain an excessive amount of silicate, and that the analysis of the ash gives a considerable pro-

Smith, ex Gordon, *Pinetum*, ed. 2 (1875), p. 221.

portion of potash, the question of decomposition is the one that needs first working out. Next, it is important experimentally to learn what absorbing properties the moss may have in collecting ammonia

is also dependent on another and quite different point—that of the retention of the fertilising properties that have been, or are about to be, imparted to the moss. In fact, the ability of the moss to

nonfertilised moss. We do not state or wish it to be inferred, that in the case of the French or "Dumesnil" manufactured moss these lines have been followed. We think it is very probable that they have not, as we observe in that moss no proofs that it has been put through any process, our own being bleached and made tougher and more durable by the mode of treatment. We also find that sphagnum is the only moss we can so treat, as it has the absorbing properties we require in a marked degree above other kinds. We note a plain word well applied by your able correspondent, Mr. Roberts—the word "ramification." That is just exactly how the benefit of moss culture can best be expressed—"the rapid ramification of the roots!" Plant growers should seek to encourage roots that take hold of every particle of the food matter, and get into close contact with all the moisture within reach. This is at least a part of the admitted course of root action under skilful cultivation, and we think Mr. Roberts expresses his convictions about aëration very lucidly. *W. Wood & Son.* [M. Ville can hardly be credited with the fact of having been the first to solve the problem alluded to. Ed.]

Foliage, cone, bract, seed-scale, and seed real size; diagram of leaf-section $\times 20$.

CAPE BULBS AND CACTI.

THESE singular and, in some respects, unattractive objects are seldom seen in private gardens. Occasionally at botanical gardens there are opportunities for a leisurely examination of them, but such a short study of the plants is of little value if one is anxious to acquire a wider acquaintanceship with the various species. Though so ungainly in appearance, and, in fact, repellent, on a closer examination it will be seen that there are many whose flowers display extraordinary beauty, and features of interest that are not met with in other classes of plants. At Fern Bank, Cadley, Preston, the residence of Mr. J. Atherton, Hon. Secretary to the Preston and Fulwood Horticultural Society, there are many species to be met with, Mr. Atherton having made this class of plants his pet study for many years.

During the month of September last, at one of the meetings of the Society, he brought a fine plant of *Brunsvigia Josephina* in full flower—a plant whose flowers many of the members present had never before seen, and all expressed indebtedness to Mr. Atherton for giving them the pleasure of seeing so rare and interesting a plant. Calling at Fern Bank a few days since I was enabled to see many other rare plants, some of which, though they have been cultivated for years, have not as yet attained to a flowering stage. Some fifty species and varieties of Cape bulbs are grown here, and it is needless to say that the flowers of many in the estimation of the proprietor far exceed in beauty those of any other plants grown.

The *Brunsvigia* is now finely in foliage, having twelve leaves upon it, which are 3 feet long and 6 inches in width. This plant has been at Fern Bank twelve years, and has bloomed three times during that period. Its history can be traced back for twenty years previous to its coming into Mr. Atherton's possession, so that here is a plant that has been watched and tended for over thirty-two years. The bulb measures 29 inches in circumference at the level of the top of the pot, and is 14 inches high from the soil to the crown.

Hæmanthus albiflos was just gone out of flower; *Hæmanthus pubescens*, pure white; and *H. tigrinus*, scarlet; and *H. coccinea* have bloomed during the past season. Another lovely thing in the autumn was *Eucomis regia*; a new *Blandfordia* grown for the past four years, is still unflowered. Other good things were *Buphane toxicaria major*, *Yeltheimia glanca*, *V. viridiflora*, *Lycoris radiata*, four years in cultivation, still unflowered; *Habranthus Hendersoni*, a large plant of *Himantophyllum miniatum splendens*, with seven spikes—a most beautiful dark coloured form; many *Criums*, and *Amaryllis*. Among the latter were a large number showing their flower-spikes. Among the Cacti we noticed a grand specimen of *Echinopsis formosa* thirty years old, *Cereus peruviana monstrosa*, *Echinopsis cristata*, *Pilocereus fossilata*, *Opuntia monocantha*, and *O. cylindrica*.

and nitrogen, and in storing the same. Then comes the consideration of the requisite proportion of chemical plant food it is necessary to charge the moss with in addition to that which it already contains. But the further perfecting of this medium

retain, and also to give off slowly, the elements of plant-food depends greatly on this treatment. That this point has been thoroughly mastered will, we think, be admitted by those who have tried the durability of fertilising moss in comparison with

Yucca filifera, *Y. quadricolor*, *Y. aloifolia* variegata, were well represented, as also the following Aloes:—*A. glaucescens*, in fine form; *A. albo-spina*, *A. soccotrina*, the last-named a grand plant with three crowns; *A. africana*, *A. albo-cincta*, very rare; and *A. albo-spinus*.

Echeveria agaveoides was a good plant, and *Doryanthes Palmieri* is a grand specimen of 4 feet in height, full of fine foliage, many of the leaves measuring 4 feet in length. Many choice varieties of *Scolopendrium vulgare* are here grown, a major form named *Athertonii* being very conspicuous among the many crested ones.

A number of plants of *Osmunda regalis cristata* were at present at rest. This is a very desirable variety. *W. Swan, Preston.*

THE HERBACEOUS BORDER.

A SELECTION OF COMMON HERBACEOUS PLANTS.

(Continued from p. 75.)

PAPAVER orientale is one of the showiest plants, producing large scarlet flowers. It is an easily grown and propagated Poppy, whose average height of bloom stalks is 3 feet.

Physalis Alkekengi, or Winter Cherry, is chiefly remarkable for its scarlet capsules, which appear in autumn, and as the winter progresses, make a cheerful display of colour in the border. Planted in a sunny situation the plant will extend itself underground, pushing up shoots all around, hence it is easily increased by division.

Polygonatum multiflorum, the British variety of Solomon's Seal, a very free flowering plant, well worth growing and doing well under the shade of trees. Though there are many species in this and other countries, the one enumerated above alone has a place in home catalogues. Continental catalogues, however, enumerate two or three other species. The value of *P. multiflorum* is greatly enhanced by the fact that it can be forced into bloom in pots, and then is a highly decorative subject.

Potentilla argrophylla, both double and single-flowered, may be classed amongst the most showy of hardy perennials, the colour of the blooms varying from yellow to scarlet and dark red. The average height is 12 to 15 inches, and the time of flowering the months of May, June, and July.

Pyrethrum roseum, the original form whence the many beautiful double-flowered forms have been derived, is a summer flowering plant that is easily grown and should not fail in the border.

Pyrethrum uliginosum, the Hungarian Marsh Daisy, is increasing in popularity, being a late flowering plant. It is suitable for border display and for cutting, as the large white flowers appear at a time when blooms are getting scarce.

Ranunculus aconitifolius flore-plenus, or Fair Maid of France, a lovely pure white double flower of fine form, flowers during the early summer. The average height is 2 feet, and the plant has the merit of succeeding well in a partially shaded situation.

Rudbeckia Newmanii is a hardy plant, resisting the effects of heat and drought, and being of dwarfer habit than some other yellow-flowered forms, is to be preferred. It flowers during July and August, and is readily grown and propagated in ordinary soils.

Saxifraga granulata flore-pleno—a double-flowered form of British Meadow Saxifrage—is a free blooming variety, worthy a place in every garden.

Spiraea filipendula flore-pleno, or double-flowered Dropwort, is a charming plant for cutting, and should not be absent from any border. The plant has an average height of 12 inches, and the white flowers are very showy when seen in masses.

Schizostylis coccinea, a Kaffrarian Irid, sometimes called Winter Gladiolus. The plant produces spikes of scarlet flowers at a very acceptable season; it is hardy, and suitable for any outdoor border. Increasing with rapidity, it requires a well enriched soil and frequent transplantation to insure full and free growth and fine bloom.

Thalictrum adiantifolium.—This and the glaucous-leaved form of the same, are very ornamental, resembling in their foliage the *Adiantums*. The growth is crowned with large heads of yellow, pink, or purple-tinted flowers, according to the species. They are easily grown, and the foliage is admirable for bouquets.

Tritoma nobilis and the lesser forms, *T. grandis*, *T. Saundersi*, and *T. uvaria*, known as Torch Lilies, are not excelled for brilliancy of colouring and massive habit by any herbaceous plant, and should be found in all large borders.

Veronica longifolia sub-sessilis, a Japanese species of vigorous growth and beauty, has leaves of a deep olive colour, and spikes of flower which are of a deep rich blue tint. The flower-spike is a foot in length, and several inches in circumference, albeit the whole height of the plant rarely exceeds 2 feet.

Matricaria inodora flore-pleno is of free growth and blooming as well as a very enduring plant, producing its flowers perfectly during the most arid weather. The double white flowers may be used for cutting, and it is readily propagated by cuttings and division.

Monarda didyma (scarlet), and its white-flowered counterpart, commonly known as Oswego Tea, are very showy neat plants for the border, averaging 3 feet in height. They bloom in summer. *W. Earley, Wford.*

FORESTRY.

THE DOUGLAS FIR AS A TIMBER TREE.

CONSIDERING the widespread interest awakened by the first thinning of the *Douglasii* plantation at Taymouth, perhaps the following will be of interest to a large number of your readers. The plantation of Honey Hill, Scone estate, consisting of 13 acres, was laid down in 1857, and is, therefore, now 31 years of age. The soil is moor, with a strong retentive subsoil, and is much exposed to the sweep of the west and north winds. It was enclosed with an upright paling proof against hares and rabbits. The Douglas firs were planted in lines at 9 feet apart, and 9 feet between the lines. The nurseries were of Larch and Scots Fir in equal numbers. All made a successful and rapid start, but during the Tay Bridge gale ninety-six trees of the Douglas Fir were blown over. Some of these were set up again; but the greater number were cut over, and their places were supplied with fresh plants. In consequence of so many Douglas firs having been blown over, the nurseries are not all removed as yet. This plantation is at present undergoing a regular course of thinning, which consists chiefly in removing nurseries that are interfering with Douglas firs. The difference in the comparative growth of the Douglas and Larch is worthy of notice. Yesterday I got three *Douglasii* trees measured:—

		Cubic feet.
First tree	30 by 11½	27 6 7
Second tree	30 by 12½	32 6 7
Third tree	30 by 12½	32 6 7

The largest Larch tree in the plantation contains 12 cubic feet, which for the age is a large growth in Larch; but the *Douglasii* trees yield a cubic foot for each year of their growth. The sale of the thinnings of the *Douglasii* plantation at Taymouth took place on the 23rd ult., and they sold at about the same rate as Larch. The largest class sold at about 1s. per cubic foot. *William McCorquodale, Jeanie Bank, January 11, in the "Perthshire Constitutional."*

THE WALNUT AS A TIMBER TREE.

A CONSIDERABLE amount of attention has lately been bestowed on the merits of the black Walnut (*Juglans nigra*) as a profitable timber tree on this side of the Atlantic. That it is well adapted for extensive culture in this country we have long ago pointed out; indeed, it is a well-known fact to those who have interested themselves in the matter, that under favourable circumstances in this country it grows more rapidly than it does in its native wilds in the United States, while it produces timber that is quite as valuable, and that sells at nearly as high a price at our British seaport towns.

The question is, however, not so much about its adaptability for planting in this country, but as to whether or not the quality of soil required to produce this Walnut would not be more profitably employed in growing other kinds of crop. Now,

from personal experience, we know that only the strongest and heaviest loam will produce this tree to perfection; in fact, it may be stated that only such land as will produce a good crop of Wheat is of any value for planting with the Walnut. We have, then, the choice of producing Walnut timber, which sells at from 4s. to 5s. per foot (three times the price of any other native wood), or Wheat, which many of our farmers grumblingly say does not pay the seed and labour!—for both plants require similar strong and substantial loam—that is, if the best results are to be obtained. It certainly seems strange that so much money should be paid annually by this country to some others on the Continent for Walnut timber for gun and rifle stocks, when it is an undoubted fact that it could be produced of quite as good quality at home; but the high price of plants, and quality of soil required to produce the best class of timber, have no doubt been the chief deterrents. A few enterprising English landowners have, however, planted the Walnut in considerable quantity, and let us hope that the results obtained will ere long induce others to follow the example, and bring this handsome tree to the front as a valuable timber producer.

The Walnut is difficult to transplant with safety, for it produces a stout tap-root, and but few of a fibrous nature, and upon which latter planters depend greatly for ease in removal. Great care is therefore necessary in the nursery management of this tree, so that it may be induced to form fibrous bushy roots, and this can only be accomplished by frequent removals, and by growing the plants in moderately rich soil.

Raising the plants *in situ* from nuts has been practised in various places, and with a great amount of success; indeed, this is the method of getting up a plantation of the Walnut that we can with the fullest confidence recommend. The method usually adopted is as follows:—Plough and harrow the ground when convenient, but, if possible, during winter or early spring; and in the following autumn plant the nuts, these being placed in lines at from 6 inches to 12 inches apart, and 18 inches between the rows. [Too near.] Careful weeding and cleaning of the ground will be required for the first few years, after which time the size and strength of the plants will kill out and quite exterminate these. Blanks in the lines may be filled up by carefully lifting the young plants from where, from their thickness, they can best be spared, and transferring them to the open spaces. Pruning and thinning at an early stage of the plant's growth is to be recommended, as these do away with the necessity of having such to perform at an advanced date, and when the trees have attained to more bulky proportions.

By paying particular attention to the young plants whilst in the nursery border, and by frequently transplanting inducing the formation of fibrous roots, perfect success in the planting out of the Walnut is a by no means difficult task; indeed, in our own opinion, forming a plantation in this way is to be recommended in preference to planting the nuts in the positions which the seedlings are to occupy as forest trees. We have planted the Walnut in quantity when a yard in height, and with perfect success, but then the plants had been reared under careful supervision, and which latter is all-necessary if the best possible results are to be achieved. *A. D. W.*

PLANTS AND THEIR CULTURE.

LILYMS.—Many of these, when cultivated in pots, are useful either for conservatory decoration or for the supply of cut flowers. Those which were not potted in autumn had better be seen to at once. They like liberal treatment—a good sound loam with about one-sixth of its bulk of thoroughly decayed manure, with a dash of sharp sand, will suit them admirably. In potting, see that the bulbs are planted deeply, as the stem throws out a quantity of adventitious roots above the crown. A good plan is to only fill the pots three-quarters full at potting time, and to fill up afterwards as the stem grows. Newly imported bulbs do better if not potted up until they show signs of growth; pot them in small pots, and partially cover them, or put them closely together in boxes, and pot off as they start. The pots are best plunged, and protected from snow and heavy rains. *Auratum*, *speciosum*, and its varieties (sometimes called *lancifolium*), and the *Easter* or *L. longiflorum* (*Harrisii*), and *L. neigheerense* are among the most useful for growing in pots.

Primulas and Cyclamens.—These plants are now

at their best, and efforts should be made to maintain them in good condition for as long a time as possible. They do best in a buoyant atmosphere with a temperature ranging from 50° to 55°, according to the state of the weather outside, and although they should have plenty of water, yet anything approaching a water-logged condition is very injurious; and double Primulas are more liable to flower and leaf dropping than singles. Remove decayed flowers and seed-vessels. If seed saving is done it is better to set apart a few plants for this purpose. Give weak manure-water twice weekly, and keep the plants well up to the light. As they are very liable to injury by sudden bursts of bright sunshine, it would be well to have a strip of tiffany in readiness to put over them. Neatly stake the flower-stalks as required. Pot off seedling Cyclamens, using about half peat and loam, with sufficient sand to keep the soil open. After potting return them to a moist growing temperature of 55°-60° as soon as the young plants have taken to the soil. A position on a shelf near the glass suits them best.

Gloxinias and Begonias.—If seeds of these have been obtained from a trustworthy source hundreds of plants may easily be raised, which will be but little inferior to named varieties. The seed-pots or pans should be quite half filled with crocks, over which a layer of rough fibre should be put; the soil must be fine and porous—equal parts of loam, peat, and sand put through a rather fine sieve answers well. Fill up to within half an inch of the top, give a good watering, and allow the water to drain off, then sow the seeds thinly on the wet soil, and stand them in the propagating house and cover the pots with a bit of tile. The pots may be frequently syringed, but do not water the soil in the pots until the seedlings are well up. As soon as ever these can be lifted with a small pointed stick they may be pricked out in pans, using similar soil to that recommended for the seed-pots.

Show and Fancy Pelargoniums.—The latest of these should now be potted into their flowering pots. It is better not to over-pot, as they make sturdier plants, and are more convenient for decorative purposes. When in smallish pots, rather stiff loam, some dried and pulverised cow-dung, a good sprinkling of bone-dust, with enough sand to ensure porosity, suits them well. In repotting it is well to squeeze the soil quite firmly—indeed it can hardly be made too firm. Water sparingly until the new soil gets well occupied with roots. Stand them thinly on the stages, and ventilate freely on all favourable opportunities. As a prevention of greenfly, occasionally syringe with weak tobacco-water.

THE ORCHID HOUSES.

EAST INDIAN-HOUSE.—If the temperature of this house can be kept up from now, until warmer weather comes, this month is a good one in which to pot any *Aerides* and *Saccolabiums* that may require it. When potting, place an inverted pot in the bottom of the other, and it will help to drain off the water well, making them also lighter to handle. In potting, fill in about the roots with large new crocks until the pot is nearly full; use only a little sphagnum down among the crocks, putting it against the points of the roots that have been growing in the moss; finish the surface with a cone of sphagnum in the usual way, but lay this on lightly, only pressing it sufficiently to keep it in place. Potted in this way it is very easy at any time to take away all the old moss from the plants, and top-dress with new, at the same time removing any dirty crocks that will come away easily, and put clean ones in their place. If the plants have foliage down to the pot, it will not be necessary to turn them out, the large-rooting *Saccolabiums* suffering much from repotting, their life often depending upon a few large branching roots, which cling to the pot, and are difficult to remove without breaking. Plants of either species that have lost their bottom leaves must be lowered in repotting, that their appearance may be improved, but it is advisable not to bury all the roots that have been growing exposed. Keep the air of the house in a moist state; give less ventilation until the plants are re-established, and very little water should be afforded them for a time, but the surface of the moss be kept damp only. Many of the *Cypripediums* of the warm-house grow freely during the winter, and some of them may require larger pots. Some species and varieties grow out of good form, and are better when sub-divided. During the

cold weather, when much artificial heat becomes necessary, yellow thrips will sometimes attack *Cypripediums* in the warmest houses; but these insects can be kept in check by thoroughly damping the under sides of the foliage and the base of the plants with an elbowed syringe, and many species will bear damping overhead. This operation should be done in the early morning, or as soon as the temperature rises to over 60°. There are several *Cypripediums* with very thick foliage, such as *C. G. odefroyae*, *C. niveum*, *C. concolor*, *C. Parishii*, *C. levigatum*, which I do not syringe at all. *Cypripedium Lindleyanum*, when robustly grown, appears a giant among its kind. A plant here, with foliage 2 feet long and nearly 3 inches wide, has sent up a spike 4 feet long, which, when all the buds have expanded, will have carried fourteen flowers; but I have noticed that only four or five flowers are fully developed at one time, and when others open the earlier ones drop off. It is growing in a house with species of *Phalanopsis*, *C. Woolford*, *Downside*, *Leatherhead*.

FRUITS UNDER GLASS.

PINES.—Plants which have started should receive an increase of temperature during mild weather, and advantage may be taken of bright sunny days to allow the temperature to rise to 90°, closing the ventilators shortly after 2 P.M., at the same time damping the interior. A handful of guano may be placed in the evaporating troughs, which should be kept constantly full of water.

Successional Plants.—Most of those Queens which were selected at the beginning of last month, and placed in a division of the Pine-stove for special treatment in order to get them to throw up their fruit early, will usually show fruit this month. The plants having been kept on the dry side until this stage was reached, as was previously advised, each plant, as it shows fruit should receive a sufficient quantity of water (weak guano) at a temperature a few degrees higher than that of the bed in which the plants are plunged. While the plants are flowering keep the atmosphere as dry as the well-being of the plants will allow, so as to prevent injury to the flowers, and consequent deformity in the fruit; 70° will be quite high enough for the night temperature during this month. A portion of the remaining succession stock may have an advance of 5° of top and bottom heat, in order to induce them to start into fruit by the end of March or beginning of April; and should any of these be very dry at the root, sufficient water should be afforded to moisten the whole ball. The portion of the stock intended to fruit later should not be encouraged to make any growth just yet. Towards the end of the month a general overhaul should take place amongst the succession plants, in order to have everything in readiness, and the soil, a good fibry loam, should be pulled in pieces and placed somewhere to get warmed. To each barrowload of loam add an 8-inch potful of soot and a 6-inch potful of Thomson's Vine Manure. At the time of potting the soil should be in such a state of dryness as to allow of its being firmly rammed in the pots with a blunt-pointed stick without becoming adhesive. The condition of the soil can be determined by lifting a handful and squeezing; when the hand is opened, if the soil remain in a lump it is too wet, if it springs back to its original state it is fit for use.

Suckers, which were placed in 6-inch pots in the autumn, should be shifted into 10-inch, and those in 8-inch into 12-inch, size of pot not being of so much importance as strict attention to the requirements of the plants during their period of growth. The pots should be carefully crocked, a little dry moss placed on the crocks, and a handful of soot over this to act as a barrier against the ingress of worms. When the plants are potted they should be replanted in the structure that they are to occupy during the summer, keeping strong growing kinds, such as *Smooth Cayenne* and *Charlotte Rothschild*, at the back of the pit; and 2 feet 6 inches space will be quite close enough, while *Queens* should be put at 2 feet asunder. The bottom-heat should be kept at about 85°, and the atmospheric warmth at about 65°, it not being advisable to excite the plants until there be an increase of sunlight. Do not water the newly potted stock for at least fourteen days, or until the roots can be discerned at the outside of the fresh compost. Any old stools with suckers which are not large enough to remove for stock should be encouraged to grow, in order that a constant supply

of fruit may be kept up. It is best to keep putting in a few suckers every month, or as soon as they become fit to remove from the parent plant. *W. M. Baillie, Luton Ho.*

THE HARDY FRUIT GARDEN.

APRICOT TREES.

The buds of these trees have plumped up very fast, owing to the mild weather of the earlier part of the month of January, and in some instances they are almost ready to burst into bloom. The bloom-buds of the Apricot are very susceptible to injury from frost when at this stage; therefore if the nailing and pruning has not been attended to as advised, it should at once be done, and the trees protected from injury by frost.

General Work.—The fruit quarters should now be dug over a few inches in depth, taking care not to injure the roots. As the digging proceeds, any trees that have been mulched should have a little soil thrown over the surface of the manure, to prevent the mulch being disturbed by wind or birds. The alleys under the walls will also require attention, as the nailing proceeds, and should be lightly dug up with a fork to the depth of 3 or 4 inches, at the same time well break up the hard clods of soil, the result of much trampling; after which the alleys should be lined out to the proper width, and this should be done at such a distance from the wall as to admit the necessary attention being given to the trees at all times.

The Orchard.—During this month attention should be given to the pruning of standard trees, otherwise they will become but a crowded mass of branches, covered with lichen in wet soils, and bearing fruit of poor quality. A well-managed orchard should be looked through yearly; by doing so the trees are kept in a healthy condition, and the crop is of increased value and goodness. In pruning, first remove the wood which is dead; all cross and badly placed branches should then be cut out, and if the heads are still crowded, some of the remaining branches may be removed. Where moss and lichen are found trees being dusted over with powdered lime (a little soot may be added to make it less conspicuous), choosing a still day for the operation, and when the trees are damp after rain. When there are many trees to prune, and the work is required to be done expeditiously, I can recommend the use of the "Standard" tree-pruner, it being a most useful implement for this purpose, as an experienced man provided with one and a pruning-saw can get through a great amount of work in a day. *A. Ward, Stoke Edith Gardens, Hereford.*

THE KITCHEN GARDEN.

SEEDS.—The earliest sowing of Celery should now be made in moderate heat. A seed-pan or two placed in a vinery where the Vines are breaking will be a convenient method for most persons. The Sandringham White is one of the best varieties for the earliest sowings as it is not so liable to bolt as some others. Tomatos for growing outdoors may also be sown now, as the principal points to be observed to obtain a good crop of fruit being to sow early, and grow the plants to a good size before planting out. I have found Gilbert's Surpasse one of the best varieties for this purpose, being a vigorous grower, a heavy cropper, and, moreover, the fruit is of first-rate quality. Preparations should be made for sowing a quantity of Peas on the first favourable opportunity. This sowing should consist mainly of the Marrow varieties, but it is well to sow a small quantity of one of the early kinds also; and in order to be prepared for another dry summer, it will be advisable, where labour is not abundant, to take out trenches as for Celery, digging in plenty of farmyard manure at the bottom of the trenches, putting into the trenches half the soil taken out, and then to sow the Peas; this will leave a shallow trench for watering and mulching afterwards, if these aids be found desirable. Radish seeds may be sown on a warm border, and covered with light litter or straw until germinated, when it must be removed by degrees, but kept in readiness for covering in the event of hard weather. A moderate bothe should also be prepared for sowing Brussels Sprouts, &c., about the middle of the month. *W. H. Divers, Kilton Hall.*

THE announcement of the death of this eminent botanist will be received in this country with as

much sorrow as it can be in his own. Apart from his scientific eminence, the clear-headed, genial character of the man endeared him to all with whom he came in contact. His vast knowledge, his untiring industry, his singleness of aim, his keen discrimination, his unselfish pursuit of science, his eminently judicial qualities, caused him to be respected even by those who exposed themselves to the sharp rapiers of his polished criticism. His work extends over more than half a century and was mainly devoted to the critical investigation of the flora of his native country, but he found time to undertake the preparation of text-books which are models of precision and elegance, he contributed much to the knowledge of tropical floras, he vastly extended our knowledge of geographical botany, he drew up numberless biographies and reviews all marked by the impress of his eminently judicious criticism. An American of Americans, a Bostonian, the colleague and associate of EMERSON, LONGFELLOW, HOLMES, MOTLEY, PRESCOTT and so many more, he was yet regarded here almost as an Englishman *par sang*. No one on this

side of the Atlantic thought of ASA GRAY as an American cousin—he was here always a brother Englishman. This arose, not only from community of language, but from close personal intercourse and entire sympathy. He combined the love of freedom and of progress of the American with the conservative instinct of the native Briton. When DARWIN published his *Origin of Species* GRAY speedily became the apostle of the new doctrine on the other side of the Atlantic. His, however, was no blind hero-worship or indiscriminating partisanship. No one had a better right to pronounce an opinion upon the questions proposed, no one could be trusted for a fairer and more impartial judgment; and so we find him ardently advocating Darwinian principles in science without sacrificing one jot of the religious opinions which came to him from his Puritan descent and surroundings. ASA GRAY was, of course, the friend, not only of DARWIN, but of all the leaders of botanical science in this country—not to speak of others, of the HOOKERS, of LINDLEY, of BENTHAM, of WARD, of HARVEY. It was a privilege on one occasion to meet him at the same table with HOOKER, and BENTHAM, and DE CANDOLLE, and many others less widely known,—a conjunction as interesting in its way as any that history can record. In truth, GRAY was a not infrequent visitor to our shores, always in company with his wife, whose graceful manners secured her as warm a welcome as that bestowed on her husband.

He passed the greater part of the last summer in this country, and then received all the honours our Universities had to bestow. Long before, of course, he had received from the societies and colleagues with whom he was more immediately in contact the recognition his talents and worth exacted; but it was not until the last year that our Universities, as representatives of the learned public, confirmed the verdict of the specialists. Oxford, Cambridge, Dublin, Edinburgh, all admitted him to the honorary doctorate, so that in one of his last letters to the writer he playfully signed himself, "Your much be-d—d old friend!"

As a horticulturist or horticultural botanist ASA GRAY, though for many years in charge of the Cambridge Botanic Garden, which was much extended under his rule, was not so well known as in other departments of botany, nevertheless that he took great interest in the subject is shown by the latest letters we received from him after his return to America in the late autumn of 1887, when he writes:—"You see that I am home again and busy," the business in this case consisting in the critical examination of several plants which he had gathered in the nurseries and private gardens of this country that he had lately visited. ASA GRAY, as will be judged from his books and memoirs, was no dry-as-dust student of dried plants; their life-history and the working of their mechanism had a charm for him, and no man was happier than he in popularising, in the best sense of the term, the discoveries of science, and creating an interest in them among the general public.

He left this country, after a prolonged visit, in September last, settled down to work, not only in his study, but on that public business which no man of his eminence can hope to escape, travelled to Washington to take part in the proceedings of the Smithsonian Institute, seemed by his friends and colleagues to be in his usual cheerful, active frame of mind, when suddenly the end came, and after lingering for a few weeks, this great good man died, on Monday last, at the ripe age of seventy-seven. America had

no truer son than he, philosophy no more noble prophet. All honour to his memory, deep gratitude for his work and his example.

A portrait and a brief sketch of his works were given in our volume for 1872, p. 1421.

CYCNOCHES CHLOROCHILUM.—To one whose love of Orchids is not confined to those whose attractions lie in their size and gorgeousness of colour, there is no section of the order which will more deserve inspection than that known as Stanhopeae. To it belong the Stanhopeas, Mormodes, Catase-tums, Coryanthes, and Cycnoches, all of which are old and well-known genera, interesting because of their wonderful shape and structure, and the remarkable arrangements in their flowers to secure fertilisation. One of the "Swan Orchids"—*Cycnoches chlorochilum* (fig. 24)—was lately flowering at Kew; in colour it is inferior to the other species, but is superior to most in the size and substance of its flowers. With the exception of the lip, which is canary-yellow and ivory-white, with an olive-green patch at the base, the flower is of a uniform greenish-yellow colour, the petals measuring 3 inches in length, and over an inch in width. The column is thin and very long, curving upwards (the flower being inverted) and enlarged at the apex, where the pollen masses are inserted; by a little exercise of the imagination it may be brought to resemble the head and neck of a swan—hence its popular name. In the morning the flowers emit a somewhat pungent but not disagreeable odour, which towards evening becomes much less apparent. When growth begins in the spring the old pseudobulbs should be potted in peat, with an addition of about one-fourth of loam, from both of which all particles of earth must be shaken; not only should the pots be quite half-filled with drainage, but pieces of broken brick and charcoal mixed with the compost also; they should then be placed in the lightest position in the East Indian-house. Water must be given sparingly until new roots are produced; afterwards freely, but carefully, always guarding against moisture lodging in the centre of the new growth. To secure a continuation of good health the plants should be kept completely at rest from the time the leaves drop off until growth recommences. This can best be attained by placing them in a cool, light, and airy position. This species was introduced from Demerara in 1838.

"**KEW BULLETIN.**"—The January number is occupied with further details relating to colonial fruit, which are of interest as showing the resources of the various colonies and affording some indication of the manner in which our home-growers may find themselves affected by colonial competition. Sir HENRY ROSCOE is cited in support of the assertion that sugar-planters have little to fear from the introduction of saccharine, which is of no value as food, though that substance may be used in cases of diabetes, where ordinary sugar is injurious.

"**THE ROSARIAN'S YEAR-BOOK.**"—With a portrait of Mr. T. B. HALL as a frontispiece this little book comes before us as usual at this season, and affords a pleasing exemplification of the old proverb, *Tot capita tot sensus*. The symposium on stocks may be mentioned in illustration, and Mr. MAWLEY—prudent man—sums up by saying that, in his opinion, "it is advisable . . . to have a certain proportion of plants of each stock, and . . . these should be supplemented by some dwarf standard and own-root Roses." Good advice, this. Mr. HALL descends upon his "Tea-house," by which he means "a house constructed for Tea Roses." This is simply an unheated span-roofed orchard-house, with a good border, as for Vines; but let not the careless amateur think that this is all that is needed; Mr. HALL's "treatment," as here recorded, shows that no little care and attention are demanded. Mr. MAWLEY contributes his customary review of the weather in relation to Rose growing—a review which is of great permanent value.

FIG. 24.—CYCNOCHES CHLOROCHILUM; COLOUR GREENISH-YELLOW. (SEE P. 144.)

THE BOTANICAL RECORD CLUB.—The report for the years 1884—1886 inclusive, specifies hitherto unrecorded localities for wild plants, with occasional critical remarks, as in the case of the curious hybrid *Vaccinium*, supposed to be a cross between *Myrtillus* and *Vitis Idea*, which is here shown to have been recognised at least twelve years ago.

THE PADUA BOTANIC GARDEN.—Some years since we published a view of this remarkable garden—memorable, among other things, for the visit of GOETHE, whose ideas of the metamorphoses of plants received an impulse from the successive stages of unfolding manifested in the leaves of a *Chamaerops humilis*, and witnessed in this garden. Many trees and plants which require shelter in more northern climes do well here in the open air, and Dr. G. B. DE TOXI has recently published a pamphlet giving details as to the more remarkable trees, their heights, &c. An *Araucaria excelsa* (under glass) has attained a height of over 70 feet. A *Vitis Agnus-Castus* is still in existence, though first noted in 1561 and again in 1650. This shrub is supposed to date from the origin of the garden in 1545. A remarkably contorted *Plane* of large size is one of the curiosities of the garden. Dr. TOXI adds a synoptical table of over a hundred of the more remarkable trees, with the date of plantation and the present dimensions, and gives a similar list, without measurements, of other trees and shrubs.

CASSELL'S "POPULAR GARDENING."—We have just received the first part of the new issue of this useful and truly "popular" publication, which is edited by Mr. D. T. FISHER. The work is well illustrated, and contains contributions on a great variety of subjects, by well-known writers, dealing with both practical and scientific gardening.

SOUTHAMPTON HORTICULTURAL SOCIETY.—We find from its report that this useful Society still maintains its position as one of the most popular in the southern parts of the country. The summer show, which fell on the August bank holiday, was visited by 20,000 persons—a number that would doubtless have been greatly exceeded but for counter attractions, and the inadvertence of the railway authorities in not providing special trains. Notwithstanding the expenses due to the Jubilee celebration in Westwood Park, and the cost of its maintenance since, the Society was able to hand over the handsome sum of £135 to aid the building fund of the new wing of the infirmary. The total expenses for the past year were £1253 1s. 6d., a cash balance of £24 4s. 4d., and a total balance of £728 10s. 1d. remaining on hand. Two significant items of expenditure appear in the account, viz., for advertising the two shows the sum of £54 15s. 2d., and for the services of a band on the two occasions a sum of £82 12s.

THE UNTIMELY FALL OF THE LEAF.—It is a circumstance well known to cultivators, that many plants, especially those which are regarded as evergreen, such as *Eugenia*, *Acacia*, *Azalea*, *Camellia*, and *Erica*, cast their foliage in large quantities when brought into the glasshouse from the open air in the early autumn months. Hitherto the reason for this vexatious malady had not been ascertained with certainty; but, as we learn from the *Hamburger Garten und Blumen Zeitung* for January, Professor P. SONAUER has recently made the discovery that it is due to vital activity at the base of the leaf occurring at an unseasonable time. As is usual in deciduous plants a layer of globular cells is formed in the leaf-stalk, the substance of which, owing to the form of the cells and the looseness with which they cohere, has so little cohesion, that when the leaf becomes heavy with moisture, drawn up by the roots, and the transpiration is small, or is entirely absent, as it is during the cool autumn months, the leaf-stalk snaps asunder at the point intersected by the layer of cells. To counteract this tendency of leaf dropping, the Professor advises in some cases that the plants should

be placed in a higher temperature, and in full sunshine, so that the balance may be restored between assimilation by the root and the transpiration by the foliage; and in other instances to reduce considerably the amount of water afforded to the roots, and for short periods to allow the plants to remain very dry. He believes that short periods of hunger are as wholesome in their action on plants as on the human system.

DR. BOSWELL.—The death of this distinguished botanist is announced. Better known under his former name of SYME, Dr. BOSWELL'S chief claim to recognition lies in his careful critical elaboration of SOWERBY'S *English Botany*, the last edition of which occupied his attention for many years and which is a veritable monument of industry and critical ability.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual general meeting of this Society took place at Anderson's Hotel, Fleet Street, E.C., on January 31—Mr. R. BALLANTINE, Vice-President, in the chair, in the unavoidable absence of the President, Mr. E. SANDERSON, there being a very good attendance of members. The annual report, which was read by the Hon. Secretary, Mr. WILLIAM HOLMES, sets forth that the past season was one of a very successful character. The September show proved both good and interesting, Dahlias and Gladioli being a very attractive feature. The November exhibition was in every respect the largest and most attractive exhibition ever held, cut blooms having been in excess of any previous year; groups arranged for effect were numerous and very fine, fruit and vegetables largely represented and of the highest quality. The January show was vastly superior to that held the previous year, and surprised by the extent and quality of the blooms all who saw it. The Floral Committee held several meetings; the attendance was always good, and every award made was only after the most careful consideration. The business meetings of the Society will for the future take place in Anderson's Hotel, Fleet Street, E.C. The report concluded by thanking the donors of special prizes, and especially the Trustees of the Veitch Memorial Fund, for their liberal grant of medals and cash. The income from all sources was £704 12s. 8d., including £169 19s. 6d. in the form of annual subscriptions; £149 1s. as donations, special prizes, &c., and £218 5s. 5d. from the Royal Aquarium. The remaining items of income include entrance fees, affiliation fees, medals and certificates, advertisements, sale of admission tickets, &c. The expenditure was £704 7s. 2d., leaving a very small balance in favour of the Society. Of this sum, £308 13s. 6d. was paid in prizes at the three exhibitions. The report having been adopted, the retiring officers and auditors were re-elected. In accordance with the rules of the Society, one-third of the committee retired by rotation, and, with one or two exceptions, the whole of the retiring members were re-elected. The Floral Committee will be appointed by the committee at the first meeting of the committee, and it is supposed that for the future one-third of the Floral Committee shall retire annually, but be eligible for re-election. Among the suggestions put forth in reference to the present year, was one that the Society should hold a provincial show, and a sub-committee was appointed to consider the matter, and bring up a report at an early meeting of the committee. The revision of the catalogue was also relegated to a sub-committee. The meeting closed with the usual complimentary votes. We think it a pity that the "Floral Committee" should be so named, and indeed lament its very existence, except for Chrysanthemum purposes.

TOMATOS AND CAPSICUMS.—The *Bulletin* n. 31 of the Agricultural College of Michigan contains an elaborate classified synopsis, with descriptions, of 110 kinds of Tomatos, with illustrations of several. The plants were grown in the open air, and allowed means for correcting the nomenclature and adjusting the synonymy. To ascertain the productiveness, the fruits from one plant of each variety were picked, counted, and weighed. By this means a

vast body of information has been obtained. The effect of cultivation has been chiefly manifested in the increased size and solidity of the fruit, but neither productiveness nor earliness have been relatively increased. The best market varieties are noted as Acme, Paragon, Queen, Puritan, Optimus, Red Valencia Cluster, Potato-leaf, Mikado, and Yellow Jefferson. Similar details are given in the case of thirty-five sorts of "Peppers," i.e., Capsicum. Onions, and Strawberries are treated in like manner, but for the present with less elaboration. Other matters of practical importance engaged the attention of the Professor and his pupils, so that the report, which is "respectfully submitted" by Professor BAILEY, is a substantial contribution to knowledge.

XAVIER GRÉGOIRE.—At the close of last year this renowned Belgian pomologist died at an advanced age, having been born in Brabant in 1802. He was a successful man of business, an active and devoted citizen, but it is principally as a raiser of seedling Pears that he is known out of Belgium. His activity in this way was prodigious; his seedlings may be counted by the hundred thousand. Of these, of course, only a small proportion have survived. A week before his death he was still engaged in selecting the seeds for future sowing. Professor RODRIGAS has devoted a sympathetic biographical notice of the veteran to the *Bulletin d'Arboriculture*.

"THE VEGETARIAN."—Under this title the first number of a weekly publication has been issued, inculcating, as its title indicates, the practice of vegetarianism. Without adopting vegetarianism pure and simple (if that were even possible), it must be admitted that a diminution of meat, and a large increase of fruit and vegetables, would be an improvement in the dietary of the majority. Excesses in any direction are bad, but it is impossible to draw a hard-and-fast line, or to infer from the experience of one man that the same regimen that is serviceable to one man will likewise be so to another. We perceive in the present number that Mr. F. W. NEWMAN by no means forswears eggs, which are certainly potential chickens, and as such should be tabooed by strict vegetarians.

SUTTON GARDENERS' ASSOCIATION.—This Association, which was formed in 1886 as a branch of the Birmingham and Midland Counties Gardeners' Mutual Improvement Association, has had during the past year a very pleasant existence. The number of its members has largely increased, and the attendance has been very good. Several papers have been read, the following being a few of the subjects taken:—Manures, exotic Ferns, soils and manures, *Amaryllis* as grown in England, and others. The Society also had two shows. The first took place on March 15. The competition was confined exclusively to members of the Association, and there was, consequently, a rather small number of exhibits. The second exhibition was the Chrysanthemum show which took place in the Town Hall, on Thursday, November 24, and prizes amounting to close upon £25 were offered for competition.

ADELAIDE EXHIBITION.—We learn that Messrs. SUTTON & SONS, Reading, have been awarded a Highest Prize Medal for their book, *Culture of Vegetables and Flowers from Seeds and Roots*.

MAIDENHEAD HORTICULTURAL SOCIETY.—The annual show of this Society is fixed for Thursday, August 16, 1888.

MR. W. BEAN, who has been the principal man in the Orchid department at Kew for the last two years, has been promoted to the post of Foreman in the Temperate Plants department. Mr. BEAN was formerly employed in the gardens at Belyoer Castle.

Cook, 94, High Street.)—*Botanical Record Club Report for 1884, 1885, 1886.* By F. A. LEES, M.R.C.S., &c. (Manchester: J. COLLINS & Co., King Street.)—*Allotments: The Solution of the Agricultural Problem.* By the Rev. W. TUCKWELL, M.A. (London: JARROLD & SONS, 3, Paternoster Buildings.)

NATIONAL SCHOOL OF FORESTRY.

THE following communication has been received by us for publication :—

Steps have recently been taken by the Corporation of Southampton, in conjunction with the Council of the Hartley Institution, to obtain the co-operation of other Corporations and local bodies throughout Hampshire in promoting a general memorial to Government relating to the proposed National School of Forestry, and the scientific and experimental work in forestry connected therewith. A Select Committee of the House of Commons reported on the subject last session, recommending the establishment, eventually, of National Forest Schools in England, Scotland, and Ireland, with a view to a general improvement in the science and practice of forestry in the United Kingdom, and also in India and the Colonies. Hampshire is essentially the forest county of England. It contains not only more public forest land than any other English county, but more than all the other counties combined. The request is therefore only a reasonable one, that the proposed Forestry School for England should be located in Hampshire, and that the scientific and practical forestry connected with it may be conducted on the very extensive Crown lands in this county. Memorials to this effect are now being sent up to the Lord President of the Council, that of the Corporation of Southampton, with which the others are for the most part identical, being expressed in the following terms :—

To the Right Honourable Viscount Cranbrook, Lord President of Her Majesty's Most Honourable Privy Council.

The Memorial of the Mayor, Aldermen, and Burgesses of the Borough of Southampton, under their common seal, humbly sheweth—

I.—That your memorialists are much interested in the general subject of practical and scientific forestry, in the preservation and greater utilisation of the Crown forests, in the general improvements in the methods of growth of timber and underwood, and in the acclimatisation in England of foreign trees of economic value.

II.—That your memorialists have heard with much interest of the proposed establishment of a National School of Forestry for England, at which Indian and Colonial pupils in forestry could also receive instruction.

III.—That the following Crown forests are situated in Hampshire and the Isle of Wight :—

1. The New Forest, comprising about 63,000 acres, by far the most extensive forest in the United Kingdom, of which by Acts of Parliament 16,000 acres can at any time be enclosed for planting, while the remaining 47,000 acres, on which trees may be growing, at any one time are to be left unenclosed.

2. Woolmer Forest, now enclosed and free from common rights.

3. Alice Holt Forest, now enclosed and free from common rights.

4. Beer Forest, now enclosed and free from common rights.

5. Parkhurst Forest, now enclosed and free from common rights.

There are also Harewood, Pamber, Stanstead, and other extensive forest lands in private hands.

IV.—That these Crown forests are situated on the following geological formations :—Lower greensand, gault, upper greensand, chalk, Reading beds, London clay, lower Bagshot, Bracklesham, and upper Bagshot beds, Barton clay, Headon beds, Hampstead beds, drift gravel, alluvium, and bog; and that consequently they contain almost every variety of soil for timber growth, and upon selected areas of which experimental plantations, with a view to the acclimatisation of suitable foreign trees of economic value, and adapted for special soils, might easily be carried out.

V.—That large areas of the New Forest are especially in want of scientific forestry, the trees in many parts of the forest being rapidly decaying owing to the restrictions applied by existing Acts of Parliament.

VI.—That the climatic advantages of the forest parts of this county make it admirably adapted for

the growth of timber, and for a great variety of work in practical forestry.

Your memorialists believe that experimental work in practical forestry such as would be necessary for a national school of forestry could be carried out on the Crown forests in Hampshire better than would be possible in any other part of England, seeing that Hampshire contains more Crown forest land than all the rest of England combined, and is easily accessible from the metropolis and other parts of England.

Your memorialists therefore pray that the proposed National School of Forestry may be located in Hampshire.

And your memorialists will ever pray.

(Corporate seal appended.)

Dated January 21, 1888.

ROSES.

SOME OTHER OLD ROSES.

ALLOW me to supplement the remarks of "Wild Rose," at p. 42, by alluding to several other old varieties of the Rose, besides those named by him. For several years past I have been collecting all the old Roses that I could meet with, and have got together a large number of varieties; but of them all there is not one that I value more than that old favourite, Celeste—not Celestial, which is the Rose that was sent to me for Celeste, whenever I gave an order for the latter to any trade grower of Roses, and I very much doubt if there are half-a-dozen men in the trade who have it in their selection. My first plants of Celeste were kindly sent me by a lady correspondent from Ireland, and from other sources I learn that this Rose is not so unknown in Ireland as in England. It is unfortunate that Celeste is only a summer flowering Rose, and not very vigorous; and as a matter of fact it is rather a weak grower, low in stature with a branching habit, with but few spines and glaucous foliage. The flower in the bud state is a real gem; the colour soft pink, fading at the base of the petals to a lovely peach colour, while its fragrance to my mind surpasses that of all other Roses. This Rose is hardly enough in the West of England, but from its appearance I doubt if it would stand a severe winter in the open in the North of England.

Gloria Mundi, or striped Cabbage Rose, I was fortunate enough to meet with in an old-fashioned garden down in the West, from which source it has since been distributed rather freely, and except that in its habit it is much less vigorous than the old Cabbage Rose, it is the counterpart of that sort in the size and fragrance of its flowers; but the petals are so numerous and thin, that they are apt to burn under strong sunshine, and wind and rain quickly spoil them. Notwithstanding these defects, I know of no other Rose that is more remarkable for its exquisite colouring; every petal is striped with an indescribable tint of violet-pink, and the stripes are so irregular that the appearance of a quite expanded flower is uncommon.

Maiden's Blush Rose has nothing particularly attractive about it unless it be left to grow unrestrained, and then it will produce large clusters of flowers in great profusion; and as the foliage is large and handsome, a good-sized bush of it is well worthy a place in a corner of the rosery. It is just the Rose to plant to overtop a low wall or to fill up an odd corner where other Roses would not grow well, as the plant is not particular as to soil provided it be not too heavy; and it will thrive if it gets but a moderate amount of sunshine.

The old Tuscan Rose is not so hardy as the Maiden's Blush, neither is it quite so vigorous in growth, and it appears to require a drier soil and fuller exposure to the sunshine to allow of its thriving properly. With us, in fairly good soil and situation, its growth is satisfactory. It flowers in large clusters, and at the same time as the Maiden's Blush, for which it is a suitable companion, on account of the contrast in colour, which is a purplish-maroon; but it is proper to remark, for the information of those who do not know these Roses, that

the individual flowers are smaller than those of the majority of the hybrid perpetuals.

The white Burgundy, a miniature Provence Rose, provides a link with old times, otherwise the variety is scarcely worthy of mention, as it has not much merit. In this neighbourhood it does not appear to be vigorous enough to withstand the climate, and although the growth is somewhat weak, the plants produce a number of fairly large pure white flowers, which are rather flat in form. We have another Rose very similar in habit of growth to this, only the flowers were much larger, and it is very full; every petal is mottled with lilac-pink on a white ground. Whether it is an old sort or not I do not know, nor do I know its name. [Unique Panaché Superb? Ed.]

Besides the foregoing there are in the collection Spong, which produces small pink flowers on neat wiry growth; also De Meaux moss, both miniature Provence; and the better known York and Lancaster Rose. I hope to say something on another occasion of some others that I have grown and of the moss Roses. I was sorry to see that "Wild Rose" did not set a higher value on the moss Rose, White Bath; for with me, growing on its own roots, in a good soil, it is without doubt one of the most effective of all white Roses for garden decoration. I have had visitors who have admired the Rose, and asked what new sort it was. Nearly all the moss Roses are very free to flower if properly treated, and there is not one that surpasses the White Bath in that respect. The flowers are unfortunately very flat when fully expanded, but the beauty of moss Roses is the partially opened bud; neither Boule de Neige nor Aimé Vibert can compare with it for effectiveness as a garden Rose when planted in the moss. It is of the purest white, and what further enhances its value is that the flowers stand the weather well. Unique, also a white flower, sometimes tinted with lake, also grows here, but it is less vigorous than White Bath. Both these Roses make good standards, but I advise all to grow them as dwarf bushes, and to plant them in well prepared soil, and then to leave them alone and to allow them to grow in their own way without any pruning. This is the treatment we give all moss Roses, and we are rewarded with plenty of flowers. J. C. Clarke, *Cotthelstone, Taunton.*

SCOTLAND.

PAISLEY AND WEST OF SCOTLAND HORTICULTURAL ASSOCIATION.

WE have before us the annual report of this Society, containing full reports of the papers read at the monthly meetings. These comprise papers on the culture of the Peach, Heath, Camellia, and other plants, which are generally excellent. Readers of papers of this sort would do well strictly to confine themselves to the record of their own observations and the legitimate inferences therefrom. When a gardener begins by referring to Latin and Greek authors, with an occasional allusion to the Hebrew Scriptures, we advise the reader to pass on to matters upon which the writer is better worth hearing. For instance, in one paper before us the reader is told that "the Latin for Melon is *Pepo*—to cook!" This is so surprising that we cannot muster courage to contest the statement that the Hebrew is *Dattich*. These form the introduction to a number of historical details, which can hardly be looked on without suspicion, and serve to throw discredit on the more practical portions of the essay.

The following arrangements have been made:—February 7.—Mr. Alexander Johnstone, Vice-President, "The Fuchsia." March 6.—Mr. Francis Davidson, gardener, 46, Moss Street, "Hardy Fruits." April 3.—Mr. Henry Maxwell, gardener, Ralston, "On the Cultivation of Annuals." May 1.—Mr. Thomas McCrorie, Kibbalehan, "How Flowers are Fertilised." June 5.—Mr. Wm. M. Moir, Vice-President, "The Narcissus." July 3.—Mr. John Suther-

land, nurseryman, Lenzie, "New Holland and Stove Plants." August 7.—Mr. John M. B. Taylor, Assistant Curator at the Free Library and Museum, "A Practical Demonstration of the Mineral Elements of Plants." September 4.—John Woodrow, jun., Esq., Neilson Institution, "The Comets." October 2.—Mr. James Walker, contractor, 19, Queen Street, "On the Formation of Bowling Greens and Tennis Courts." November 6.—Mr. John Williamson, Bishopston, "The Culture of the Strawberry." December 4.—General meeting.

AMERICAN NOTES.

THE "AMERICAN GARDENERS' MONTHLY."

We learn that, in consequence of the death of Mr. Marot, the *Gardeners' Monthly* will in future be fused with the *American Garden*. The *Gardeners' Monthly* has been edited by Professor Meehan since 1858, and has been remarkable for the intelligence and originality with which it has been conducted. So far as possible, no mere routine practice has been urged in its columns, unless a good reason could be found for it. Professor Meehan's extended experience as a nurseryman, his frequent and lengthy travels, and his knowledge of plants in a state of Nature as well as under cultivation, gave him the opportunity of acquiring information of the most varied character, and of which his readers had the benefit in the *Gardeners' Monthly*. It is to be hoped that horticultural literature may still be enriched by his communications.

INARCHING.

SOME time since (July 23, 1887) we published an interesting article from a Danish gardener in Sweden relating to the effects likely to be produced by grafting or inarching. About the same time we also published an account of some similar experiments made by Mr. Roupell. In the explanation of the consequences and effects of grafting there is nothing to be done apart from carefully devised, accurately performed, and well recorded experiment. Theory is useful as a guide to experiment, but it is obvious that by itself it is in this case useless. Mr. Andersen's experiments were conducted with the object of ascertaining what, if any, influence the leaves of one variety would have upon the berries of another variety united to it by inarching. Mr. Andersen shall tell his own story:—

"My experiments were done in three different manners, but rough diagrams will best explain the way it was done. At *a* (fig. 25) leaves from another variety are inserted above the bunch; in *b* the bunch with three or four of its own leaves is put on another sort; [Unfortunately the bunch is omitted in the engraving, but its position may be imagined at the * on the left of the sketch between the two leaves. Ed.] at *c* the bunch is put on another sort with none of its own leaves at all. The inarching was done about a fortnight before the blooming period, and they were cut as shown on diagram just when the thinning was finished. There were several examples of each class, and they all went on well, with a single exception. The sorts used were Van der Lahn, Trentham Black, Duke of Buccleuch, Black Hamburg, Duchess of Buccleuch, and Muscat Hamburg. The sorts are planted in the order named, so there was a good selection of different colours and flavour, and the experiments were varied in several ways. The Vines are from eight to nine years of age, so there was a good crop of normal bunches to compare with. When the Grapes were ripe there was not much difference to be seen between the normal ones and those that were inarched, some of the latter were a little later and smaller, but not much; there was no trace of colour on the white sorts that were put on black varieties, and on testing there was no flavour to be detected in such unflavoured sorts as Van der Lahn and Duke of Buccleuch put on Trentham Black; nor Muscat flavour in Duchess on Muscat Hamburg—not even in the experiments of class *c*, which I consider the most decisive. That the inarched bunches (especially in classes *b* and *c*, where they were above an union), experienced a little delay in ripening and growth is no wonder considering the difficulties the circulation had to overcome at the union. I was

rather surprised that they succeeded so well as they did. The most interesting fact gained by these experiments is that a bunch of Grapes, cut away from all connection with its own sort at an early period and left alone to grow and mature on a quite different sort (even without a leaf of its own, as in *c*), is still able to be true to itself in all respects—shape, colour, and flavour. This complete independence is astonishing when we consider that all its work has to be done with leaves of another sort. The Editor's impression (as expressed with my earlier note, p. 108, July 23)—that the bunches derive their main supply of food [up to a certain time] from the old canes from which they spring, and that the work of the newly-produced leaves is mainly, but not entirely, to act as feeders to supply stores in the old wood, and not to feed the young bunches except to a limited extent—I cannot accept at all. It may be true at an early period, before the young leaves are full grown and able to work, but from the thinning period to the ripening we cannot call the leaves newly-produced or the bunches young. That the leaves are wanted—and wanted strong and healthy—in the said period, to get good Grapes, especially as regards colour and flavour, is well known to all Grape growers; even the best

stock. The individuality of the bud is preserved. Still, there are occasional exceptions, and in the study of these exceptions will probably be found the clue to the explanation of the phenomena. Increased size, variations in degree of precocity and of hardiness, are changes that take place commonly, so that even in ordinary cases it is probably nearer to the truth to say that the changes that occur are not of a directly tangible character, than to say that no change at all takes place. The subject has assumed increased interest of late years from the discovery of the passage of threads of protoplasm from one cell to another through minute pores, whereas formerly the notion prevailed that each cell was a closed organism, through whose walls only fluid could pass by osmotic action. Would that some of our histologists and physiologists would investigate grafts from this point of view.

FLORISTS' FLOWERS.

NEW VARIETIES OF DAHLIAS.

THE following notes on the Dahlias of 1887 were made during the season at the Handsworth Nurseries, Sheffield, where these were grown, together with over 500 others, comprising the best of the older varieties. Owing to the dryness of the season, and the smallness of the plants, about one-third of the new ones did not bloom until very late in the season; consequently it was not possible to decide as to their merits as flowers fit for exhibition.

SHOW VARIETIES.

Bendigo (Turner) is a purplish-crimson flower of perfect form, good habit, and very constant; it is a lovely variety, of the same form as Lord Chelmsford, and its only fault is, that of a very soot petal. It grows to 3 feet high.

Colonist and the following are of Messrs. Keynes & Co.'s raising. This has flowers of chocolate and fawn colour, and is quite a distinct and new colour in Dahlias, but it will not rank high as an exhibition flower, owing to its reflexed and pointed petals; still, as a decorative variety, it is one of the best. Four feet: the average height is 6 feet.

Crimson King has deep crimson-scarlet flowers, and nice dwarf habit, making it certainly one of the best varieties. It is very constant, and is one that is sure to be seen in winning stands during the forthcoming season. The height is about 3 feet.

Defiance, a dark scarlet, is a beautiful variety, coming on early in the season. It requires to be thinned severely. Height same as the last-named.

Ellipse has bright orange-scarlet flowers, and is one of the finest scarlets sent out for many years. It is a good grower. No new variety has shown so much improvement in its flowers, as they continue to open each being better than the earlier ones. It grows to a height of 4 feet.

Golden Eagle is a yellow flower, deeply edged with scarlet, of fine form, with a good shell-like petal, and is likely to hold its own as an exhibition flower. It is of full size, and very constant, and the height is about 3 feet.

Illuminator has dark red flowers, beautifully shaded with orange. A pretty variety that should make an excellent back-row flower in a stand, but it has not the kind of petal that is required in a first-class show flower. The height is about the same as the last named.

King of Purples.—A very fine purple, and beautifully formed flower, but which, owing to the great warmth of the season, came of small size. If this variety can be grown sufficiently large it will be a valuable addition. It is rather taller than the last-mentioned: 4 feet.

Victor is of a dark maroon colour, and gives promise of being a valuable addition on account of its colour, and size, which is not over large. It is constant, and of similar height to *Illuminator*.

The next five varieties were raised by Messrs. Rawlings & Son, viz.:—

Mrs. Theobald, a rose-coloured flower with beauti-

FIG. 25.—INARCHING THE VINE.

In *A* leaves belonging to a variety different from that bearing the bunch are inserted above the bunch; in *B* the bunch * and leaves of one variety were both placed on another stock; in *C* the bunch only was inarched on another stock without any leaves of its own.

old wood will be of little use at that period—it will start the Vines well, and carry them some way, but not even through the blooming. Moreover, here the sort put on has not got any old wood at all of its own; it is simply independent. This fact (at least I consider it as such) is, as many other facts in plant-life, rather difficult to explain, as, for instance, the transport of starch from the leaves to other parts of plants, tubers or roots for instance, or of the force with which the sap in spring is sent upwards in trees, and many more riddles. *M. P. Andersen, Gunnarstorp, Sweden.*

Inarching has been practised from time immemorial, and in various countries. Our illustration at p. 149 (fig. 26), which we owe to Mr. Woodrow, shows how, at the present day, the natives of India make use of the process by inarching good varieties of Mango upon inferior stocks.

So far the vast bulk of evidence is similar to that mentioned by Mr. Andersen. No tangible change is effected in the scion by its union with a different

fully formed petals and outline, but which will, I think, be too small for exhibition. Three feet in height.

Mrs. David Saunders has a ground colour of rosy-lilac, which is slightly edged with white; it will prove a useful show flower of large size, but is rather flat and should not be thinned out much or it will become coarse. The height is about 4 feet.

Queen of the Belgians.—A delicate cream-coloured flower, the inside of the petals being soft pink. A very valuable exhibition variety, quite distinct from *Mrs. Gladstone*. It must not be over-fed early in the season, or the flowers will come coarse and hard-eyed. It will make a noble back-row flower, possessing every good property. I have seen six well finished and large flowers on a plant all ready together. Height 4 feet.

R. T. Rawlings is one of the best yellows raised, but not, as the raisers say, "the best." It is very constant, and the height is about 3 feet.

J. T. West.—This variety bears a good name, and is a thoroughly trustworthy variety for the exhibitor, besides being distinct in colour, yellow heavily tipped with purple. It is very constant and of medium size.

Nellie Tranter (Tranter).—Clear yellow, constant, nice form; but I cannot agree with the raiser in calling it the equal of *Mrs. Gladstone*: another season will prove this. A very useful flower: 3 feet high.

Willie Garratt (Garratt).—Bright cardinal, of fine form and habit, very constant, and in every way first-rate. Much admired by everyone who saw it, especially by old florists.

FANCY DAHLIAS.

The following are both *Keynes & Co.*'s productions:—

Edmund Boston.—Orange, heavily striped with crimson. This is a very fine fancy, and should be in every collection. It is certainly one of the best and most constant ever raised.

Magnet.—Lilac, densely striped with rich purple; a very useful flower, and very constant as a fancy.

SIMPLE DAHLIAS.

These are well represented, and are in great demand as cut flowers. The finest of the new ones of 1887 were *Chameleon*, *Dandy*, *Don Juan*, *Eccentric*, *Gazelle*, *Hector*, *Iolanthe*, *Lady Jane*, *Mignon*, and a variety raised in the neighbourhood, namely, *Geo. Harris*.

SINGLE DAHLIAS.

All the leading varieties, but the most distinct is a variety sent out by Messrs. Fisher, Son & Sibray, last year, and called *Masterpiece*, blackish-maroon, the ends of the petals distinctly tipped with white, like *Coleus*. The *Shah*, with broad solid petals, stands a long time when cut, and is very constant.

CACTUS DAHLIAS.

are well represented as to sorts, but the name is misleading, as there is only one *Cactus Dahlia*, *Juarezii*; the remainder are simply decorative varieties, and for habit and free flowering there are many amongst the show and fancies that will more than hold their own with them. What is wanted is the *Juarezii* type of flower, with the dwarf habit of the best show and fancies—varieties with flower-stems long and strong enough to hold their flowers well up above the foliage. *J. H. W., Sheffield.*

PLANT NOTES.

ALPINIA OFFICINARUM.

This is a Chinese Ginger-like plant, and is the source of "Galangale," an aromatic stimulant, used for indigestion but not much known in England. A plant of it is now flowering at Kew. It has a Ginger-like rhizome, from which spring leafy stems 2 feet or more high with leaves arranged distichously from top to bottom; the leaves are about 1 foot long by 1½ inch broad. Flowers in a short terminal erect spike exactly as in *A. nutica*, but on a smaller scale; they are white, the tip scoop shaped, over 1 inch long and

wide, with numerous lines of red radiating from a yellow throat. *A. nutica* is also flowering now at Kew. It is similar in habit and size to *A. nutans* but the flowers are on an erect spike instead of a drooping one, as the name *nutans* implies. *W.*

DURANTA.

The figure and note recently published in the *Gardeners' Chronicle* concerning these plants are of a somewhat tantalising character. The figure was taken from a plant flowered in India, and the cultural directions given are unfortunately not what would lead to the flowering of these plants here. Has any one flowered a *Duranta* in England? They are grown as stove plants in a few gardens, but they will not flower. In the West Indian colonies and even at the Cape these plants are used as hedges or specimen shrubs, much as we grow *Privet* here; and the effect is about the same till the plants flower, and then!

FIG. 25.—INARCHING THE MANGO.

Imagine long arching wand-like branches covered with beautiful little sky-blue flowers, waving about in the wind, and lasting a long time. If we could get these plants to behave properly and flower with us as they do when under more natural conditions, they would constitute a new feature among stove plants. Have they ever been tried in the extreme south of England, growing them outside all summer and lifting and protecting them in winter—in short, under *Bouvardia* treatment? I have an idea that they would be a success. *W.*

TRYPHIA SECUNDA.

This plant is now flowering at Kew. It is one of the tiniest of Cape Orchids, and one of the least attractive. The tuber is small and fleshy, and it produces two shining green, fleshy, heart-shaped leaves a little more than 1 inch long. The scape is erect, simple, 5 inches high, not much thicker than a horsehair, and it bears eight flowers clustered about the top. The flowers suggest those of the common

Chickweed, being white with four linear segments, and a three-lobed lip; they are ¼-inch across. The species is a native of the Cape on the east side, where it grows on wet rocks and in other moist places. Botanically this little plant is interesting, but it possesses no true beauty whatever, not even as much as our *Ladies' Tresses*. Horticulturally it is worth knowing only that one may avoid it! *W.*

TREES AND SHRUBS.

ORNAMENTAL BERRIED TREES AND SHRUBS.

(Continued from p. 116.)

The broad-leaved Spindle Tree (*Euonymus latifolius*) is certainly one of the most showy of autumn shrubs. When suitably placed, it forms a large bush of usually a dozen feet in height, and during the autumn and winter months is thickly studded with its conspicuous fruit. These are composed of pink, pendulous capsules, which, when ripe, open and reveal the orange-coloured seeds, at which period they are particularly attractive.

Crataegus pyracantha Lalindii is one of the most attractive berry-bearing shrubs in cultivation, for not only are the berries of the brightest and most desirable colour, but they are borne in such profusion that the branches are literally coated with them.

The Mountain Ash (*Pyrus Aucuparia*) is, perhaps, too common for any but the lover of the truly beautiful to fully appreciate; and yet, when weighted down with its bunches of conspicuous fruit, it is certainly an object well worthy of our warmest admiration. Then it grows almost anywhere, the breezy hillside where scarce a particle of soil is to be found, or the shady woodland with its wealth of decaying vegetable refuse coming alike to this most unobtrusive of plants.

Roses of different kinds must on no account be omitted from our list of ornamental fruited shrubs for some species bear these in abundance and of the most conspicuous and pretty colours.

R. rugosa can well hold its own as a bright fruited species, and one that is of great value in ornamental plantings. The berries are large, of good shape, very freely produced, and of a most desirable and enticing orange-scarlet colour.

The European Box Thorn (*Lycium barbarum*) is of *Privet*-like habit, and bears a rich abundance of crimson fruit. It is a capital seaside shrub, and braves the fierce, and long-continued salt-laden winds with perfect impunity.

The Snowberry (*Symphoricarpos racemosus*), with its pretty white fruit, is totally distinct from almost any other shrub. The berries associate nicely with those of any of the before-mentioned shrubs, indeed afford a pretty contrast to the reds and scarlets.

The Fly Honey-suckle (*Lonicera*), as seen just now in some of the Kentish lanes and chalky downs, is truly of both interest and beauty, and we were quite charmed the other day to see an old fence draped with the twining stems and rich profusion of reddish berries of this interesting native plant.

Mauls' Cydonia, during the autumn and early winter months, is thickly studded with its golden fruit, these being tinged externally, but usually only one side, with a rich pink, which offers a nice contrast to the golden-yellow of the fruit generally.

The Service-tree (*Pyrus Sorbus*) is another extremely pretty shrub or small tree, not only on account of the white downy undersides of the leaves, but brownish fruit, which is produced in abundance.

Berberries.—Amongst these are several berry-bearing plants of merit, and being perfectly hardy, of free growth, and extremely floriferous, they should find places in every garden. *B. Darwini*, whether in flower or fruit, is truly a delightful shrub; while *B. aquifolia*, with its broad-angled leaves, is usually studded with fruit during autumn and early winter.

Eugenia Ugni, with its abundance of purple edible fruit, must find a place in our list. It is not hardy everywhere—a matter much to be regretted, for it is

certainly as ornamental a plant as has yet been sent to us from the coast of Chili. *A. D. W.*

EARLY FLOWERING HARDY SHRUBS FOR WALLS.

Outdoor flowers at this time of year being scarce, the undermentioned plants are worthy of notice. *Chimonanthus fragrans* and *C. fragrans grandiflora* are both deciduous shrubs, and, as the specific name implies, sweet-scented. In the South of England they are quite hardy, and succeed on east, west, or south walls, the latter being preferred for very early flowers. Of the first-named we have an old established specimen growing on the east side of the mansion which will not be at its best for three weeks, whilst one of *C. f. grandiflora* growing on a west wall has been in flower for the past fortnight, and promises to continue for some time. Both varieties do well, it is said, in a deep sandy loam, and I can certainly answer for their growing in a calcareous soil. Immediately after flowering is the best time to prune them. Cut back all shoots which have produced flowers to within an inch of their base, cutting out all weak growth, in the case of young plants, leaving the leaders intact until these have filled their allotted space. During the summer months allow the young growth to be quite free, so that the wood may get well ripened, as on this depends the quantity of flowers they will produce the following year. Propagation is effected by means of layering in the autumn.

Garrya elliptica.—This is certainly one of the most attractive of flowering hardy evergreen shrubs in the winter time, and deservedly merits a wide distribution. It is difficult to say why one so seldom meets with it, seeing that it was introduced into this country so long ago as 1828. It is very hardy, as with well ripened wood it will stand the test of frost at zero in the Southern Counties; add to this its freedom of flowering at a time of year when flowers are scarce, and we have here a plant which should be found in most gardens. The inflorescences are produced from the axils of leaves and points of young growth of the previous year, and consists of long pendulous catkins 4 to 6 inches in length, and of a silvery-green colour, forming a pleasing contrast with the dark-coloured ovate-shaped foliage. It is admirably adapted as a wall-plant on western aspects, as is here shown by a five years old plant having covered a space of 90 square feet. After flowering—or say the end of February—is the best time to prune the shrub, the operation simply consisting of cutting out lateral shoots and thinning out old ones where they are too much crowded. Nothing further will require to be done throughout the summer excepting on walls the nailing or tying in of the leaders, all breast-wood being allowed to grow untouched. Propagation may be done by layering in the autumn.

Jasminum nudiflorum is too well known to need any lengthy comment. Suffice it to say, its yellow flowers are very acceptable in January, and the plant is worth growing in all gardens where wall space can be afforded it, and that it is not fastidious as to soil or aspect. Prune the shoots after flowering by cutting them back to a short spur and thinning out old ones where there is overcrowding. *J. Horsfield, Heytesbury.*

THE FLOWER GARDEN.

OUTDOOR FERNERIES.—Where these exist any cleaning, planting, and renewing the labels should be done. Do not for the present remove last year's fronds from deciduous species, as these are Nature's best protection against the cold. The following are rather tender species:—*Cyrtium carvotidum*, *C. falcatum*, *C. Fortunei*, *Lastrea atrata*, *L. opaca*, *L. Sieboldii*, *Polystichum proliferum*, *P. setosum*, *Struthiopteris orientalis*, *Woodwardia japonica*, and *W. orientalis*. Where new work is in progress it should be completed with as little delay as possible so that all planting may be done before the end of the month. In the making of outdoor ferneries no pains should be spared at the outset to render the work of an enduring character; space will not admit of details

being given, but I would mention three points as being indispensable to avert failure, viz., the natural shade afforded by a moist situation, and soil of a suitable character. If the natural soil of the place is unsuitable for Ferns, substitute other, consisting of sandy loam, leaf-mould, and peat—a peat possessing all good qualities being that in which the roots of wild Ferns abound. In planting the arrangement should be of such a nature that something of interest may be seen at any time of the year; to accomplish this, evergreen species should be planted freely, and do not, as is too frequently the case, allow deciduous kinds to predominate. Suitable accommodation in the way of rockwork should also be provided for a few of the smaller growing species, such as the *Asplenium*; *Ceterach officinarum*, and some of the *Scolopendriums*, and it would be of additional interest if on a portion of the rockwork running water could be introduced, near to which those two British "filmies," *Hymenophyllum tunbridgense* and *H. unilaterale*, might be grown. *J. Horsfield, Heytesbury.* [In making purchases of hardy Ferns, either native or exotic, the services of a grower of repute should be procured, as it is found that some species which succeed in one part of the country, are not equally adapted for planting in other parts. Ed.]

HOME CORRESPONDENCE.

Correspondents will greatly oblige by sending early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Photographs or drawings of gardens, or of remarkable plants, trees, &c., are also solicited.

THE ROYAL HORTICULTURAL SOCIETY.—While agreeing with Mr. Woodbridge (see p. 118, Jan. 28), that it is desirable to secure the "sympathy and support of practical gardeners," yet I am afraid that the way in which he proposes to accomplish this will not meet with the approval of gardeners in general. Inasmuch as it is proposed to only "confer upon a limited number of the leading gardeners throughout the country the honour of Associate of the Royal Horticultural Society," I feel sure that any limitation scheme or process of selection, other than that which would admit of every gardener being able to obtain, by his own individual efforts, without the nomination or court influence of anyone; anything less must fall short of the mark. I quite agree with Mr. Woodbridge when he says that of "gardeners' names which occur in garden Directories there are men of various degrees of ability." This, of a necessity, will always be so; but he further proposes that this distinctive honour be only awarded to "those gardeners who had attained to a considerable degree of eminence in their profession." Just so; but what constitutes "a considerable degree of eminence?" I am afraid it is too frequently gauged by considerations other than what is achieved in practical gardening; that is, his eminence may only, or in a great measure, be due to the light reflected from his employer's coffers. Now to confer the honour of "Associate" on such an individual would not only be a sheer mistake, but also a manifest injustice to other gardeners less favourably placed, yet who may know considerably more about the practice and principles of their profession. And this leads me to the conclusion that the only fair and absolutely just method of selecting recipients for the honour and title of Associateship should be according to their knowledge of the practice and principles of gardening. There would be no difficulty in arriving at a pretty correct estimation of whether the candidate was deserving the honour. As there are always men on the Council of the Royal Horticultural Society who are in every way qualified to act as examiners, they could issue a short syllabus of what candidates would be expected to know, and then put a few test questions as they presented themselves for admission. I think it would be advisable not to make a high standard to begin with. An Associateship obtained in the way I have indicated would then become a reliable certificate of ability. Moreover, this scheme would place it within the reach of all who chose to qualify themselves; and whether they be gardeners to the King, Queen, my Lord, duke, or squire, it matters not. To all who gained an Associateship in this way I should, as Mr. Woodbridge says, give free access to the Society's committee meetings, gardens,

&c.; but I think if they subscribed half-a-guinea annually they should be entitled to all the privileges which at present belong to a two-guinea Fellow. If this were carried out, I do not see any necessity for having a guinea membership; such member could then either become an Associate or a Fellow. Should these few crude remarks take practical shape I should be glad to try for the Associateship. *F. Ross.*

I am watching the affairs of the Society with the greatest interest, and trust that we distant country-folk may come in for a share in the benefit of the new programme. A convenient exhibition day in the middle of the week, instead of Tuesday, would, for instance, be a boon. This, of course, is a trifle, but small matters sometimes either help on or prevent success. In any case, may all prosperity attend the Society on its new lines, and may the shadow of horticulture never grow less! *S. Wales.*

The suggestion put forth by Mr. Woodbridge is well-intentioned. He hopes to see real interest in the Royal Horticultural Society promoted in the minds of the gardeners of the kingdom generally by establishing an order of special merit. I have a poor notion of honours of this nature generally, but putting that aside, and admitting that such a proposal merits consideration, the point is, first, what body of persons is there to be found who can fitly and impartially select the 500 honoured men from the 5000? and, second, in what way are the respective merits of each man to be gauged or estimated in making the selection? And here I am thinking after all very much less of the 500 honoured in this perfunctory way—and I admit there are far more in the ranks of British horticulture worthy the honour—than of the 4500 left out of the selection, and each of whom, by the very act of omission, is dubbed as second-rate or inferior, not from faults, but because his merits have not found favour with a particular body in London. Really this proposal would have, if adopted, the effect of creating 500 dubious friends, whilst it would as certainly create four times that number of censorious critics. Let us have the half-guinea memberships, whether termed Associates or not; then there will be no arbitrary process of selection, which would hardly run on Darwinian lines; but every one who desires the appellation might secure it for the small annual charge of 10s. 6d. However, I am far more anxious to become a member of the Royal Horticultural Society on the half-guinea basis than to be found even one of the select 500, because I desire to give the Society some tangible support. This simple plan would save much complication. Under Mr. Woodbridge's proposal we should have half-guinea members, ditto Associate members, and finally Associates paying nothing. *Spade.*

I quite agree with your correspondent, "Spade" (p. 118), that this is a time when "a little practical help is worth a lot of sympathy," so far as the above Society is concerned; and if "Spade" will set an example of his own teaching, by handing to you, Mr. Editor, the sum of £5 for the old Society, I shall, of course, feel in honour bound to follow such a good and generous example. What does your correspondent mean by "officialised?" and is the "less restraint" to be applied to the income or to the expenditure of the Society? As to my becoming "Hibernianised," I can only say that as a Saxon in the land of the Celt, I have many reasons to feel thankful, and shall always openly testify to the many kindnesses and courtesies which have for some nine or ten years been extended to me on the Irish shore by "all sorts and conditions of men." The point in my letter to which "Spade" takes exception was to recommend a botanist for botany, and that a good experienced man of business should be obtained to manage and resuscitate the Society's affairs. Can "Spade" improve on this suggestion? *F. W. Burbidge, F.L.S.*

If the Society does not recover from its difficulties it will not be from want of advice. Among the remedies proposed I consider the one suggested by Mr. Woodbridge at p. 118 a step in the right direction if carried out in a liberal spirit. If the Society is to accomplish more in the future than it has done in the past it must be made a national society, and in order to do this effectually some such scheme as that which Mr. Woodbridge proposes must be carried out before a general interest in the Society's welfare can be raised. I have lived the greater part of my time at a considerable distance from London and in various parts of the kingdom, and find that in many instances people know very little, and possibly care very little, about the Royal Horticultural Society, simply because they have no connection with it whatever, but if connected

with the Society in a way like that suggested by Mr. Woodbridge a man would feel bound to further its interests in every possible way amongst his friends, also by contributing to the meetings, and in various other ways as the opportunity arrived. It is impossible for most of those at a distance to get to more than one or two meetings during the year, and the reports through the Press of the work done by the Society are necessarily very brief. The success of the Royal Agricultural Society has been quoted as an instance of what might be done by the Royal Horticultural Society, but besides the advantages the Royal Agricultural Society derives from its well-paid Secretary and regular provincial meetings it appeals to a much larger class than the Royal Horticultural Society can do. There is also much more capital influenced by its work, and the times are fast becoming strictly utilitarian. *W. H. Divers, Ketton Hall.*

GARDEN PEAS.—Praiseworthy as are the efforts made to reduce the number of varieties of our garden Peas I fear few of my brother gardeners, who have to supply a large and constant demand even from June to October inclusive, will have the courage of "Daring" in pinning their faith to one variety, or even "Spade's" trio, under all conditions of situation, soil, and climate. My own timidity in the matter would prevent my relying on less than the following half-dozen, three tall and three dwarf:—William I., Criterion, Champion of England, Gladiator, Marvel, and Omega—the first and last relied on solely for early and late crops respectively, and the intervening ones filling up the gap for main crops. The foregoing, as a whole, for productiveness and quality are seldom equalled, and never excelled; but for exhibition as well as for home show (for many of us are expected to grow as large Peas, even if not such croppers as our neighbours), I must yet add another trio, of larger podded kinds, of good flavour, but not so prolific and continuous as those already named. Heading this trinity I place Duke of Albany, later Evolution, and latest Sturdy. From repeated trials of the latter, I have hopes of it proving a fitting companion to Omega, with the additional merit of larger pods. In exposed situations, as here, where autumn winds are prevalent, I think tall varieties for late crops are not profitable, hence my leaving out Ne Plus Ultra. All tall late kinds have been discarded here in favour of dwarfs—Omega to wit. *J. R.*

—Gardeners who wish for a good supply of Peas from June till November will do well to try the following kinds. We have grown them for many years, can speak from experience, and are certain they cannot be surpassed. Early: Carter's No. 1, Sutton's Emerald Gem, Laxton's Prolific, Bishop's Longpod. Mid-season: Scimitar, Veitch's Perfection, Dixon's Dwarf Mammoth, Pride of the Market—2½ to 3 feet in height. Late: British Queen, Ne Plus Ultra, Victoria Marrow, Matchless Marrow—6 feet high. *J. M.* [Peas, like other plants, vary with locality, so that what will suit in one place will not grow satisfactorily in another. *En.*]

CYCLAMEN COUM.—The most beautiful spring flower now out at Oakwood is Cyclamen Coum; it is growing in full sun in a bed containing old mortar. After many experiments I am sure that this treatment suits hardly Cyclamens better than some other we have tried. Both flowers and leaves are finer and brighter in colour. *George F. Wilson, Heatherbank, Weybridge Heath, January 27.*

HYBRIDISATION.—I put on record in the *Gardeners' Chronicle* some time ago an occurrence which seems to have so direct a bearing on "A. B.'s" question, p. 121, (if I understand his question aright) that I venture to re-state it. In 1880 I crossed Iris Balkana (Janka) with the pollen of I. Cengiali (Ambrosi), the latter being a variety, or perhaps rather a subspecies of I. pallida. I obtained fifteen seedlings, which I described in the *Gardeners' Chronicle*, giving at the same time what seemed to me valid evidence that I had effected a real hybridisation. One of these seedlings after throwing up, in a pot in a greenhouse, a scape with a single terminal flower, and a lateral one, the peduncle of the latter arising from the axil of a large spatheaceous bract, threw up later, at the end of May or in June, a second scape with a single terminal flower, the spatheaceous bract at the node below bearing no lateral flower. Having cut off this terminal flower above the bract I observed later on, in August, with surprise, that the cut scape had not, as is usual withered, but remained green up to the cut end. The base of the spatheaceous bract seemed to be swollen,

and on examination I found that in the axil of the bract was, not a pedunculate flower-bud, but a sessile growing bud with a nascent rhizome, a young leaf, and the hint of a rootlet. I cut off the scape below this bud, and so potted the bud. In a short time I had a vigorous young plant, which, however, was unfortunately lost sight of. Now it is a very common occurrence for certain bulbous Irids (*e.g.*, *Sparaxis*, *Freesias*, &c.) to bear a bulbil in the axil of a leaf or bract; but I have hitherto never seen this in any member of the genus *Iris*, bulbous or otherwise, not even in *Sisyrinchium*, which is the connecting link between *Iris* and *Moraea*. Of course in this case the "vegetative" bud did not start quite fresh; it replaced an aborted flower-bud. But if there be any truth in the view of sexual organs being the outcome of diminished vegetative energy (whatever that may mean), the incident may still be regarded as an example of increased vegetable activity, and it occurred in a hybrid. I have seen nothing like it in other Irids; but I may add I have not seen it repeated in other hybrids. I did not attempt to raise seed from this particular plant, but its brethren, though, undoubtedly to my mind—hybrids, were not sterile. I have since raised two generations from them, and a third is probably about to be—*paulo post futura*. They were less fruitful than the male parent (Cengiali), which is a prolific seed bearer, and about as, or perhaps, rather better seed-bearers than the mother (Balkana), which does not very readily go to

FIG. 27.—CURRANT BUD HALF. (SEE P. 153.)

seed. My experience in hybridising Irids, and the careful watching of several cases of what appear to me to be undoubted hybridisations, has led me to the conclusion that, in their case, no general statement can be made as to the sterility or robustness of growth (vegetative energy) of hybrids. These two things seem to me to depend, not on the mere fact of the hybridisation, but on the conditions of the hybridisation, such as the relative affinity, comparative characters, &c., of the two parents. I am inclined to think, however, that hybrids have a greater tendency to transgress morphological laws than offspring born in more lawful wedlock. Like a certain editor, they lean towards teratology; and the sport I have described seems to me an evidence rather of this than of any superabundance of "vegetative energy." *M. Foster.*

THE TURNER MEMORIAL PRIZES.—I do not think it was needful on the part of Mr. J. Douglas that he should offer any apology for the announcement of the manner in which these prizes are to be bestowed this year. Mr. Turner was a man of large grasp, and I have found him quite as deeply interested in a Peach or Pear, a Pea or Potato, as in an Auricula, Carnation, or Dahlia. When the Memorial Committee was originally formed, I joined with others heartily in suggesting that fruits at least should share in the benefits of the prizes, and I am glad to see that such suggestions have been acted upon by the sub-committee and trustees. The reputation enjoyed

by Mr. Turner and the Royal Nursery, Slough, was far from being alone due to flowers. Both were almost as well known and appreciated for fruit trees, for Coniferae and shrubs, and for scores of other things which go to form a general nursery stock, and in all of which Mr. Turner took hearty interest. That these memorial prizes are of a terminable nature should make them in the estimation of gardeners all the more valuable, as only a certain number of persons, and within a restricted number of years, can win them. I trust the action of the committee or trustees in sending one prize to York and another to the Crystal Palace will, by the excellent competition produced, be more than amply justified, and that the fortunate winners will regard their Turner Memorial prizes as worthy horticultural honours. *A. D.*

RHODODENDRON FERTILISATION.—I have *Rhododendron argenteum* in flower just now, and I would feel obliged by any one sending me some flowers with pollen that would make a good cross with argenteum. I have had this plant for certainly twenty-five years, but owing to careless looking after it only flowered two years ago—one bunch of about eighteen flowers. Now it has thirty-two bunches, some of them with thirty flowers, and extremely handsome. So much for having had it attended to. It is about 10 feet high. *R. S. Newall, Fernleean, Gateshead.*

CARNATION.—I send for your inspection a Carnation plant attacked by a sort of spot or fungus, which I am afraid looks very much like *Cladosporium*. It is on a few plants I had sent me, and fortunately kept them by themselves. I have dipped them twice a day for about three weeks in soapy water, tobacco-water, covered them with sulphur and Fir-tree oil, and nothing seems to destroy it. Can you give me any information on the matter—what it is, its cause, or remedy? *Carnation*. [You are correct in supposing your Carnations to be attacked by a *Cladosporium*; it is *Cladosporium echinulatum*, described and illustrated in the *Gardeners' Chronicle* for August 21, 1886. Your plants are also attacked to a serious degree by the Rust fungus, or *Uredo*—probably the *Uredo* form of *Puccinia Dianthi*, or of *Uromyces Behenii*. It is not (as might have been assumed from its habit) *Uredo caryophyllacearum*. We can give no further remedy than the one in the number of the *Gardeners' Chronicle* mentioned above. The treatment you have already employed without effect shows how obstinately some parasitic fungi adhere to life. You must remember that these fungi are able to spread to various other species of *Dianthus*, *Lycnis*, &c. *W. G. S.*]

CHRYSANTHEMUMS "An Anxious Enquirer."—As a grower who has attended many of the shows this season I consider the six best varieties of Japanese Chrysanthemums are:—Avalanche, H. Cannell, W. G. Drover, E. Molyneux, Carew Underwood, Maggie Mitchell. *Foreman.*

SIX JAPANESE CHRYSANTHEMUMS FOR EXHIBITION.—It would not be safe to depend upon six varieties only of Chrysanthemums to supply that number of blooms, for the reason that some sorts do not always succeed so well as do others; therefore it is best to allow a margin by growing more sorts than are really required of distinct varieties. For the information of "An Anxious Enquirer," I give the names of twelve of the best, placed in the order of merit. In my opinion, in this form any one of the number given can be selected, taking the names as they appear, and still securing the best:—Madame C. Audiguer, deep mauve; Belle Poule, white, edged with rosy-purple; Boule d'Or, yellow and bronze; Jeanne Delaux, dark velvety-brown; Edwin Molyneux, purple-crimson and gold; Mr. H. Cannell, soft yellow; Mrs. H. Cannell, snowy-white; Fair Maid of Guernsey, white; Triomphe de la Rue des Châlets, salmon-red; Criterion, amber; Mdlle. Lacroix, white; Ralph Brocklebank, primrose-yellow. *E. Molyneux.*

MEDLAR JELLY.—The Medlar jelly which Mr. T. F. Rivers exhibited at South Kensington lately, and which was so much approved by the Fruit Committee that it was awarded a First-class Certificate of Merit, aroused a great deal of interest on the part of those present at the meeting of the Royal Horticultural Society. It was pronounced to be a rich and palatable jelly, and it served to indicate the possible creation of a new and useful industry in the direction of fruit preserving. Mr. Rivers stated that a few years ago a Hawthorn hedge in the Sawbridgeworth nursery was cut down

and grafted with the Royal Medlar, a free-bearing variety of nice acid flavour, the fruit being of medium size. In the manufacture of the jelly the Medlars are taken when they are quite ripe, by which I understand that the period chosen is when the fruit is softening somewhat. When Medlars are newly ripe the fruit is "not eatable, but in a few weeks it begins to soften," and it is at this point that the fruit is best adapted for the purposes of jelly: but not allowing it to become brown and pulpy. The Medlars being selected they are washed and placed in a preserving pan with as much water as will cover them, and are allowed to simmer gently until they become a pulp, and it is necessary to stir the mass occasionally to prevent its becoming burnt, and so adhering to the pan. The fruit, being made into a soft pulp, is then strained through a jelly bag. To every pint of juice is added 1 lb. of lump sugar, though some might prefer to add three-quarters of a pound. It is then boiled for an hour and a half or rather less, and then, when ready, put into glasses and jelly shapes. In a communication received from Mr. Rivers he hints that it might be well to boil the jelly a little longer than in the case of the Sawbridgeworth experiment, probably to ensure a greater consistency. But the sample seen at South Kensington appeared to be all that could be desired, and possibly the finished jelly would harden in course of time. It is certainly an interesting experiment, and Mr. Rivers ventures to think a wide popularity is in store for it when the process of manufacture is made widely known. *R. D.*

CHRYSANTHEMUM JUDGES.—It would be interesting to know if the half-dozen men "Spade" mentions (p. 85, January 21) are the only competent judges of Chrysanthemums, or is that the reason their names appear so frequently as judges at the principal London and suburban shows? Surely there are provincial growers equally good judges, but possibly they have no one so eager to trot them out as "Spade" appears to be. I am not an exhibitor, but think with many others, that judges should be growers. *S.*

THE RAINFALL AT ROTHAMSTED, HERTS, AND CARDINGTON, BEDS.—In the average columns the sign (—) signifies below, and the sign (+) above the average record:—

	Rainfall, 1887.		Rainfall of 1887. Over or Under Average.	
	Rothamsted, Herts.	Cardington, Beds.	Rothamsted, 34 yrs.—1854-86.	Cardington, 41 yrs.—1846-86.
January	2.39	2.04	- 0.18	+ 0.30
February	0.95	0.72	- 0.91	- 2.40
March	1.76	1.33	+ 0.09	+ 0.02
April	1.19	0.88	- 0.85	- 0.78
May	2.35	2.34	+ 0.05	+ 0.52
June	0.71	0.83	- 1.72	- 1.21
July	0.79	0.38	- 1.83	- 2.01
August	1.04	1.24	- 1.52	- 1.07
September	3.11	1.87	+ 0.45	- 0.31
October	1.69	1.31	- 1.52	- 1.13
November	3.41	1.87	+ 0.63	- 0.02
December	1.95	1.20	- 0.57	- 0.44
Total	21.05	16.01	- 7.88	- 8.53

The rain-gauge of Sir J. B. Lawes, at Rothamsted, is 420 feet above the sea-level, and the rain-gauge of Mr. J. McLaren, at Cardington, is 109 feet above the sea-level. Rothamsted is considered to be *within* the "high rainfall" district, and Cardington is *without* the "high rainfall" district. The table shows that Rothamsted registered 21 inches during the year 1887, being 7.88 inches below the average of the past thirty-four years, whilst Cardington, which is without the high rainfall district, received but 16 inches of rain during the year 1887, or 8.53 inches less than the average of forty-one years. The most notable character of the year just ended is therefore the light rainfall. Only in 1870, when 14.87 inches were measured, has there been less rain, since the records were began at Cardington. At Rothamsted, 1887 gave the lowest rainfall with three exceptions, namely 1854, 1858, and 1864, when 19.4, 20.0, and

18.6 inches were registered respectively. The year 1870, which recorded the lowest rainfall at Cardington showing 1.14 inch less than 1887, gave at Rothamsted 21.7 inches or three-tenths above the rainfall of the past year. *J. J. Willis, Harpenden.*

GARDENERS' ORPHAN FUND.—The suggestion made at p. 85 by your correspondent, "J. H.," as to what may be termed "gathering up the fragments," or odd pence, in boxes duly labelled "Donations for Gardeners' Orphan Fund" is every way excellent. If such boxes were hung up in conspicuous places about the work-sheds in gardens, and alongside each box the printed sheet issued by the committee summarising the benefits of the Fund, there can be no doubt but that a considerable amount of help would result from the practice. I would go a step further, and that visitors to the garden might have a chance of contributing I would advocate the placing of a second box in some house or entrance most frequented by them. As a matter of course we must first get the permission of our employers to allow of the boxes being placed, and next the aid of our men, which will best be obtained by giving them to understand that the work is theirs, and that whatever contributions are put in the box will be recorded to their credit; at the same time the assurance should be given that no one is to feel that he is under the slightest obligation to contribute. I so strongly approve of "J. H.'s" suggestion that I mean to set about getting the boxes at once. *W. Wildsmith.*

FREESIA CULTURE.—The communication of J. G. Hill, p. 107, respecting these charming flowers is, I consider, an extremely valuable one, opening up, as it were, a field of new light in their cultural requirements. I was quite unaware of their semi-aquatic nature, and most heartily thank Mr. Hill for myself and the many other of your readers to whom, no doubt, the hint will be equally new, interesting, and valuable. "Freesias 3 feet high and a sheet of bloom" would not only be a perfect picture, but would astonish thousands of admirers of this exceptionally delicious flower. But why has Mr. Hill kept so valuable a hint in obscurity so long?—for it appears some years have elapsed since the arrival of the original thirty now developed into such unwonted grandeur came to hand? But, having once attained the dimensions given, the next question is, where may they end? What a magnificent picture a few such pots would make among foliage plants for conservatory decoration. I note one particular in Mr. Hill's remarks, and it is this, that Mr. Bartlett prefers to give his Freesias water freely several times a day (notwithstanding their semi-aquatic nature) rather than immerse them in water or partly so—with a view to avoid stagnation, no doubt, which makes their treatment, in this respect at least nearly equal to that of the Disas. Mr. Bartlett's treatment, as against that generally pursued, illustrates clearly the vague notions which still exist as to the proper treatment of certain plants, and I, for one, shall turn over a new leaf in their treatment; and I can only recommend growers of these Freesias to follow Mr. Bartlett's example. For commercial purposes it is, however, absolutely necessary to dry them off entirely, but of this gardeners in large private establishments will have little to do. I have frequently noticed how quickly newly imported bulbs of these start into growth after planting; and imported Callas, which are dried to the core, are another instance of water-loving plants doing likewise. There is, I feel sure, a great future for the Freesias, especially as cut flowers; for were it possible to produce them in quantity and in succession, they would, beyond doubt, soon occupy a foremost position among choice flowers; and any hints of exceptionally good culture will be welcomed by many besides the writer. The freedom with which they reproduce themselves, and the cheap rate at which they may be obtained, are points highly favourable to their much more extensive cultivation. *E. Jenkins.*

HARDINESS OF LAPAGERIAS.—It is interesting to hear of this fine climber doing so well outside with Mr. Hazel. A few years ago we had a strong piece of Lapageria alba growing here, fully exposed on a north-west aspect, and it frequently stood 16° and 18° of frost without injury, but the limit of endurance was reached when we got 22°, and the plant perished completely. There is (much) in the hard nature of the foliage and stems of Lapagerias to favour the idea that they would prove hardy. The favourable southern aspect Mr. Hazel's plant occupies will doubtless tend to give it greater hardiness, as the

growths will be better ripened than on a north-west aspect, and it may prove capable of resisting a greater degree of cold than 22° of frost. A slight protection—and that only in severe weather—is all that is necessary to ensure the safety of Lapagerias during ordinary winters in all the southern counties. Although our plant grew and flowered very freely outside, we always found 4° of frost completely destroyed all expanded blossoms; and as we are always liable to have slight frosts during the flowering period of the plant, we think it right that this fact should be made known, to prevent disappointment to those who may be tempted to plant it outside. During favourable weather the flowers set freely outside, and we gathered many pods of fully ripened seeds, and have now a dozen plants raised from seed of *L. alba*, grown outside. All the seedlings have flowered, and every plant has proved to be *L. rosea*, though there are slight differences in the depth of colouring, and in the length of the tube. *J. Roberts, Gunnersbury.*

THE WEATHER.

Accumulated temperature indicates the combined amount and duration of the excess or defect of temperature above or below 32° F. for the period named, and is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

THE PAST WEEK.

THE following summary record of the weather for the week ending Jan. 30, is furnished from the Meteorological Office:—

"The weather has been somewhat changeable, but finer than of late in most parts of the kingdom. A good deal of cloud prevailed at times, with some showers of rain, sleet, or snow. In Scotland the rain and snow were heavy, but in England and the greater part of Ireland the falls were slight.

"The temperature has been a little above the mean in 'Scotland, E.,' but below in all other districts, the deficit in the 'Channel Islands' being 3°, and in 'England, S.W.,' 4°. The highest of the maxima, which were registered during the earlier days of the period, ranged from 48° in 'England, S.W.,' to 56° in 'Ireland, S.' The lowest of the minima were recorded on the 30th, when the thermometer fell as low as 10° at Geldeston, and to between 14° and 18° at many of the other English stations, between 18° and 22° over Ireland and Scotland, and to 30° in the 'Channel Islands.'

"The rainfall has been more than the mean in the north and east of Scotland, and equal to it in 'Ireland, N.,' but less in all other districts.

"Bright sunshine shows a very general increase, the percentage of the possible amount of duration varying from 15 in 'Scotland, W.,' to 34 in 'England, S.,' 35 in 'Scotland, W.,' 39 in 'Ireland, N.,' and 'England, S.W.,' and 41 in the 'Channel Islands.'

MEAN TEMPERATURE OBSERVED AT CHISWICK DURING THE WEEK ENDING FEB. 11. (AVERAGE OF FORTY-FOUR YEARS.)

ENQUIRIES.

"He that questioneth much shall learn much."—BACON.

THE "MELON PEAR" (*Solanum guatemalense*).—Where can seeds of this be obtained? X.

NOTICES TO CORRESPONDENTS.

AMARYLLIS: R. H. B. If water was withheld hitherto, the green condition of the foliage is due to the roots having drawn some nutriment from the leaf-bed. It is still possible to get the foliage ripened by withholding water, and maintaining a cool temperature; the rest they will get will be short.

ARTIFICIAL MANURES: K D. Malt dust is an excellent dressing for grass land at the rate of 30 bushels to the acre, and for Wheat at the rate of 40 bushels, for Turnips and Barley in the same proportion as for grass. The dust is usually harrowed in, but it is much improved as well as made easier to distribute if it be soaked in liquid manure. Spent Hops, by themselves, have a low manurial value, but are useful as a dressing to Turnips, Rape, Cabbage, to keep off the "fly." Of the value of stale yeast we know nothing, but it must necessarily be small.

BOOK: *Prentice and Medicus. Domestic Floriculture. Window Gardening, and Floral Decorations.* By F. W. Burbidge. (W. Blackwood & Sons.)

CORRECTION: In referring to the habit of *Grobya Amherstiae* (p. 106), the genus *Lælia* is mentioned; it should have read *Cœlia*; and for *Thrinax* read *Thrinia*, at p. 104, line 17.

GLASS CORRIDOR AND LOUNGE: *Medicus.* The creepers that you may plant outside and bring inside through holes made in the walls, if the temperature intended to be maintained be that of a cool house, are Vines of any kind—those with leaves that die off a good colour are pretty; *Jasminum revolutum*, *J. grandiflorum*, *Passiflora cœrulea*, *Clematis indivisa*, and any of the hybrids of Messrs. Jackman, Standish, and others; the smaller growing Ivies; *Fuchsias*, strong growers like *corallina* and *corymbiflora*; *Roses*, *Maréchal Niel*, *Gloire de Dijon*, *Catherine Mermet*, *Climbing Devoniensis*,

Isabella Sprunt, and other strong-growing varieties, especially Tea-scented ones; also *Madame Lacharme*, *Madame Despres*; any of the climbing *Honeysuckles*, *Myrtles*, *Tecoma jasminoides*, *Camellias*, and *Aristolochia Siph.* In any case, the stems would require thorough protection from frost at the part exposed above-ground, and it would be advisable to cover the roots with leaves or cocoa-nut refuse to keep frost out of the soil. The border in which they are planted should have at the least half a day's sunshine.

GREENHOUSE: L. B. The height being what it is, it would not be advisable to plant out any shrubs; but creepers might be planted in properly prepared borders, and these might be allowed to grow on the sides, ends, or roof, in a way that would not greatly impede the light from reaching the plants beneath. Rockeries might be formed in some of the angles, and planted with Ferns, bulbs, mosses, and otherwise made use of for flowering plants. Treated as a greenhouse it would require, to keep out frost and maintain a temperature of 40°–45° at night, two rows of 4-inch pipes running all round and beneath the side tables. A flue in a house of this peculiar form would not be easy of construction, and would be less satisfactory than water-heating. Some part of the centre space could be occupied with hardy Palms, *Camellias*, a Tree Fern, *Choisya ternata*, *Ficus elastica*, *Plumbago capensis*, *Myrtles*, *Eugenias*, *Acacias*, *Fuchsias*, *Phormium tenax*, *Lilies*, &c.; and the side benches with any flowering plants you might choose to grow. The sanded floor might remain; it is pleasanter to walk on than lattice-work, and can be made of varying width, according to fancy.

HELLEBORE: L. S. A form of *angustifolius*, and a very fine one, quite worth propagating.

HAMENOPHYLLUMS, TODEAS, AND TRICHOMANES: *Subscriber.* The first and last succeed when planted in a mixture of fibry peat, moss, and broken sandstone; a small quantity of charcoal may be added. *Todeas* do well in the same kind of soil, but substituting fibry loam for the moss, and adding a little sharp sand.

INSECTS: *John Wilson.* Your Black Currant shoots are infested with a mite which, in our issue for August 7, 1869, we fully described with an illustration, which is here reproduced (fig. 27, p. 151). In that article it was stated: "Badly infested trees ought evidently to be pruned in autumn. We would recommend, where possible, the picking off of old dried buds in August or September, as it is evident that the newly formed buds must become infested almost as soon as they are well developed in the early part of the autumn. Possibly the dressing of the shoots at that period with a thick coating of lime and soapsuds might either prevent the females from crawling to the young buds, or the hatching of the eggs if laid in the old buds." The creature seems to be very active north of the Tweed, but is not unknown this side of the border.—T. W. S. The insects which infest your stove belong to one of the many species of cockroaches (*Blatta* sp.), which are imported from hot climates with plants. The best way to destroy them is to place deep saucers, partly filled with water, where they occur, with bits of wood extending from the ground to the edge of the saucers, up which they will creep and fall into the water. I. O. W.

LUCULIA ORATISSIMA: A. Pakenham. The temperature of a *Camellia*-house is too low for this plant, and would lead to debility, as seems to have set in with scanty flowering two years ago. Place it in an intermediate temperature, say 50°–58°, at night, with 10°–15° higher by day.

MICA CLAY: *Westfield.* It may be possible to obtain this substance from the Bedford Conservatories, Covent Garden.

MUSHROOMS DESTROYED BY WOOD-LICE: J. H. S. Procure boiling water, go suddenly into the Mushroom cellar with a light, and pour the water all round the chink that is found between the bed and the walls. If this be repeated at intervals, and no hay be used to cover the beds, the marauders will be almost exterminated in a few weeks.

NAMES OF PLANTS: G. M. R. 1, *Davallia canariensis*; 2, *Onychium lucidum*; 3, *Pteris argyrea*; 4, *Adiantum hispidulum*; 5, *Asplenium biforme*; 6, *Doodia caudata*.—A. *Collyer.* Specimen insufficient.—W. *Alison.* *Calliphurria subedenata*; often erroneously called *Eucharis candida*.—B. A. C. 1, *Asplenium bulbiferum*; 2, *Pteris*

tremula; 3, *P. serrulata*; 4, *Polypodium aureum*; 5, *Pteris cretica albo-lineata*; 6, *Begonia fuchsoides*; 7, *Libonia penrhosiensis* X.—G. W. *Rogers.* The *Lælia* is *L. acuminata*. *Dendrobium Kingianum albidum*.—W. J. A. *Dendrobium nobile*, *Cœlogyne cristata*, simply.—W. E. I, *Epidendrum Endrieesi*; 2, *Oncidium Wentworthianum*; 3, *Pittosporum undulatum*. We do not understand to what you refer by "Egyptian pots."—E. R. M. *Euphorbia Lathyris*.

RAFFLESIA: W. A. G. Substantially correct. It has been figured in the *Gardeners' Chronicle*, but is not in cultivation.

SEEDS.

LONDON: February 1.—Messrs. John Shaw & Sons, seed merchants, of 37, Mark Lane, E.C., write that the trade for farm seeds remains steady, though momentarily quiet. No alteration as regards values can be noted, rates being made at full prices. For English red Clover seed, however, somewhat lower figures are accepted. Alsike and white Clover move off slowly on former terms. Perennial Rye-grasses are this season exceedingly cheap; there is room for a rise in this article. Timothy continues in short supply. Sanfoin also is in narrow compass. Canary and Hemp seed realise last week's rates. In spring Tares there is more doing, and holders are raising their limits. Other articles offer no subject for remark.

FRUIT AND VEGETABLES.

COLUMBIA: February 1.—Fair supply of fruit and fresh vegetables; trade moderately good at fair prices. Potato trade slack. Quotations:—Cauliflowers, 1s. 6d. to 3s. per dozen; Savoys, 1s. 6d. to 2s. do.; Cabbages, 1s. 3d. to 1s. 9d. do.; Brussels Sprouts, 2s. to 2s. 6d. per half sieve; Turnip-tops, 1s. 3d. to 2s. per sieve; Sprouting Brocoli, 1s. 3d. to 1s. 6d. do.; Spinach, 1s. 6d. to 2s. do.; Carrots, 1s. 6d. to 2s. 6d. per dozen bunches; Turnips, 2s. to 2s. 6d. do.; Greens, 2s. 6d. to 3s. 6d. do.; Beetroots, 1s. 6d. to 2s. do.; Celery, 9d. to 1s. 3d. per bundle; Rhubarb, 6d. to 8d. do.; English Apples, 3s. to 6s. 6d. per bushel; American Apples, 15s. to 21s. per barrel; English Onions, 8s. to 9s. per cwt.; foreign do., 7s. to 8s. per bag of 110 lb.; Carrots, 28s. to 42s. per ton.

STRATFORD: February 1.—The supply and trade have been good. Prices:—Savoys, 5s. to 7s. per tally; Greens, 2s. 6d. to 3s. per cwt.; Turnips, 3s. to 3s. 6d. per dozen bunches; do., 35s. to 50s. per ton; Carrots (household), 40s. to 50s. per ton; do., cattle feeding, 28s. to 34s. do.; Parsnips, 6d. to 1s. per score; Mangels, 18s. to 22s. per ton; Swedes, 20s. to 24s. do.; Onions (Dutch), 7s. to 8s. per bag; do. German, 9s. to 10s. per case; Apples (English), 3s. to 6s. per bushel; Watercress, 6d. per dozen; Brussels Sprouts, 2s. 8d. to 3s. per half sieve; Rhubarb, 1s. 9d. to 3s. per dozen bunches; Parsley, 3s. to 4s. per dozen; Onions, 2s. 6d. to 3s. per dozen bunches; Spanish, do., 8s. to 9s. per case.

POTATOS.

BOROUGH AND SPITALFIELDS: January 31.—For best samples a steady trade, second qualities full supply, and lower. Quotations:—Regents, 60s. to 105s.; Hebrons, 80s. to 120s.; Magnum Bonums, 45s. to 95s.; Champions, 50s. to 70s. per ton.

COLUMBIA (East London): February 1.—Quotations:—Beauty of Hebron, 100s. to 110s.; Magnums, 50s. to 80s.; Regents, 60s. to 90s.; Champions, 45s. to 65s.; Victorias, 50s. to 65s. per ton.

STRATFORD: February 1.—Quotations:—Scotch Regents, 80s. to 95s.; Scotch Magnums, 70s. to 85s.; best English, do., 60s. to 70s.; fenland, 45s. to 55s. per ton.

JENSEN'S

Every grain fertilizes because the Guano is perfectly
pure. It is most economical, one part of Manure to
100 parts of soil being ample for garden use.

FISH-POTASH

FISH-POTASH contains Ammonia, Phosphates and
Potash in large proportions, which are the principal
elements of fertilization.

GUANO.

GUANO—2-lb. Tins, 1s.; in Bags, 7 lbs., 2s ;

By Royal Letters Patent.—Carbon Cones.

LETHORION
 (VAPOUR CONE).

For the distribution of certain principles in a state of vapour, in Greenhouses and Conservatories, whereby their active properties are most closely brought into direct and intimate contact with vegetable productions, for the purpose of DESTROYING PARASITIC LIFE with a certainty hitherto unachieved, and without hurt or prejudice to the most delicate and fragile organization of plant life. The old system of fumigating with cloth or paper is now quite unnecessary.

Cone.	cu. feet.	PRICES.	Per case.

"MYTICUTTAH"

(REGISTERED).

PATENTED in GREAT BRITAIN, FRANCE and GERMANY.

As the S. M. Co.'s "Standard" Tree Pruner is admitted to be the best Pruner for work a distance from the ground, so will the two "MYTICUTTAHS" prove the handiest and most powerful for Pruning and Trimming close to the ground, such as the removal of shoots from roots of trees; also Shrubs, Fruit and Flower Bushes, Vines, and other climbing plants, &c. Their construction enables prickly Shrubs and Bushes to be Pruned without lacerating the hands or wrists, even if gloves are not worn. They will with ease cut the hardest wood growing without injuring the part left by splitting and drawing the sap several inches up and causing decay, as other implements are known to do.

For Illustrated PRICE LISTS of above and other NOVELTIES in PRUNING TOOLS, FRUIT and FLOWER GATHERERS, &c., apply to the

STANDARD MANUFACTURING COMPANY,

ST. ALKMUND'S CHURCHYARD, DERBY;

NEURALGIA

"is indicative of a low condition of health, which must render those affected susceptible to Diseases. Neuralgia indicates a low state of vitality, and nothing so exhausts the system as Pain that prevents sleep and agonises body and mind. It is not wise to suffer the distress caused by this malady without seeking relief."

WHY SUFFER FROM NEURALGIA?

When you can get a box of

For 1s. 1 1/2d.; post-free, 1s. 3d. From Chemists, &c. Facsimile of label. ENT. STA. HALL. If your Chemist has not got it, ask him to order it for you.

A LADY writes:—"The use of one powder of Mack's NEURALGIA CURE gave me prompt and permanent relief."

A GENTLEMAN writes:—"I have suffered from Neuralgia for two years. A friend sent me a box of MACK'S NEURALGIA CURE. The third powder gave me relief. I am telling every sufferer from Neuralgia I meet about it."

The Trade supplied by NEWBERRY, BARCLAY, SANGER, EDWARDS, &c., London; JOHN THOMPSON, Liverpool; THOS. McMULLAN & Co., Belfast, and other Wholesale Druggists and Patent Medicine Dealers, from whom any Chemist can have it by return of post.

"A veritable encyclopaedia of gardening knowledge." Gardeners' Chronicle.

Reissue in Sevenpenny MONTHLY PARTS, of CASSELL'S POPULAR GARDENING. A Comprehensive Practical Guide to the Successful Cultivation of Flowers, Fruit, and Vegetables.

Nature with Science.

ILLUSTRATED CATALOGUE of over 100 Distinct New Varieties of Vegetable and Flower Seeds collected from all parts of the world, and now offered for the first time.

Lawson Seed and Nursery Company, Limited (an Incorporation), BANGHOLM NURSERIES.

WANTED, a TEMPORARY MANAGER. Apply in writing with testimonials, to CHIENE AND TAIT, C.A., The Liquidators, 67, George Street, Edinburgh.

A GENTLEMAN, whose garden is larger than he requires, wishes to find an experienced thorough GARDENER, single, to live at the lodge, who would keep the Garden in first-rate order, supply the House with Flowers, Fruit, and Vegetables, and sell the Rest of the Produce instead of wages.

WANTED, at a large Provincial Establishment a MAN, thoroughly competent to undertake the Management of the Glass Department.

WANTED, a reliable MAN, to aid in the Development of a Nursery and Florist's Business. Must be a successful Propagator of Indoor and Outdoor Stock.

WANTED, a good GARDENER, for Flowers and Vegetables; two Greenhouses. Unmarried. Churchman. Bass or tenor voice for surplined Choir.—Rev. J. G. BRYNER, Oldde Okeford, Dorsetshire.

WANTED, a GARDENER, to take Charge of Nursery.—Write, stating wages required, experience, and where last employed, to Mr. HINE, 5, Waterloo Place, Pall Mall, S.W.

WANTED, for a good Nursery in Lancashire, a thoroughly competent INDOOR FOREMAN, or PLANT GROWER and PROPAGATOR, to Produce Cut Bloom in Quantity. Good at Wreaths and Bouquets. State wages and references to P. W. T., Gardeners' Chronicle Office, 41, Wellington Street, Strand, W.C.

WANTED, a thoroughly competent INDOOR PROPAGATOR, to Grow for the Trade.—Address, stating particulars and salary required, to SECRETARY, Botanic Gardens, Southport.

WANTED, an active young MAN, used to Grapes and General Nursery Work.—H. HENDERSON, Kemble Nursery, Kemble Road, Tottenham.

WANTED, a Married MAN, with little or no family, to Assist In and Out of the Houses, used to Fires and Potting; 16s. per week with cottage; all overtime paid in the summer.—R. CLARKE, Market Gardener, Twickenham.

WANTED, in a Seed Shop, a MAN accustomed to the Execution of Orders. Must have a good general knowledge of Seeds, accurate and prompt in the Execution of Orders.—SEEDS, Gardeners' Chronicle Office, 41, Wellington Street, Strand, W.C.

WANTED, AT ONCE, COUNTER HAND, for London Trade.—Apply, stating experience, and salary required, to WHOLESALE, Gardeners' Chronicle office, 41, Wellington Street, Strand, W.C.

WANTED, a FLORIST'S ASSISTANT and SALESWOMAN. Must have experience and good reference, with full particulars.—E. G., Gardeners' Chronicle Office, 41, Wellington Street, Strand, W.C.

WANTED, a MAN, of good character for a Nobleman's Garden, able to Glaze, Paint, and do Carpenter's Work. Preference will be given to one who can sing in a Church Choir.—IRELAND AND THOMSON, Nurserymen, 81, Princes Street, Edinburgh.

WANT PLACES.

RICHARD SMITH AND CO. beg to announce that they are constantly receiving applications from Gardeners, seeking situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—St. John's Nurseries, Worcester.

SCOTCH GARDENERS.—JOHN DOWNIE (of the late firm of Downie & Laird), Seedsman, 144, Princes Street, Edinburgh, has at present on his List a number of SCOTCH GARDENERS, waiting re-engagements. He will be pleased to supply full particulars to any Lady, Nobleman, or Gentleman requiring a trustworthy and competent Gardener.

GARDENER (HEAD).—Seventeen years' good practical experience in Forcing of Fruit, Flowers, and Vegetables. Excellent testimonials.—W. MASTERS, Highnam Court Gardens, Gloucester.

GARDENER (HEAD); age 35, married, no family.—A GENTLEMAN wishes to recommend his Gardener, who has been with him eleven years; thoroughly experienced in the profession. Good cause for leaving.—J. D., 51, Friary Street, Tonbridge.

GARDENER (HEAD).—Age 33, married, no family; thoroughly experienced in all branches. Four years' good character from present situation. Good references from other situations if required.—W. CAMPIN, Queensberry House, Richmond, Surrey.

GARDENER (HEAD).—Age 37; twenty-two years' experience; thoroughly practical in every department, and capable of undertaking the Management of a First-class Establishment. Good character and testimonials.—R. G. WATERMAN, Woolton, Liverpool.

GARDENER (HEAD).—Age 32; eighteen years' experience in Early and Late Forcing of Fruit, Flowers, and Vegetables, also Flower and Kitchen Gardens. Excellent character and testimonials.—Chas. Arthur Tolley.—Apply, Mr. CYPHER, Exotic Nursery, Cheltenham.

GARDENER (HEAD).—Middle-aged, married; Scotch. Wishes an engagement for May term. Sixteen years in present situation. Thoroughly practical in all branches of his profession.—WM. SAMSON AND CO., Seedsmen, Kilmarnock.

GARDENER (HEAD); age 35, married.—A GENTLEMAN would be pleased to recommend his late Head Gardener as a thorough practical, experienced, and trustworthy man, capable of Managing a First-class Establishment. Eighteen years in some of the leading places. Teetotaler.—J. F. RAGGETT, 14, Rindell Road, Paddington, W.

GARDENER (HEAD); no encumbrance.—Mr. W. BISHOP, late Gardener to the late Sir E. Jodrell, Bart., and many years at Bylaugh Park, will be pleased to treat with any Lady or Gentleman requiring the services of a first-class all-round Gardener.—HEAD GARDENER, The Grove, Teddington; or, Head Gardener, Wesley Hall, Bury St. Edmunds.

GARDENER (HEAD); age 33, married, no family.—W. J. IRELAND, late of Nostell Priory, and previously with the Marquis of Headfort, is open for re-engagement. Thoroughly conversant with all matters relative to Horticulture. Protestant. Strong and healthy, and not afraid of exerting himself. Left at own request. Testimonials of the highest order for character and ability.—24, Cambridge Street, Eccleston Square, London, S.W.

GARDENER (HEAD WORKING), where one or two are kept.—Age 26; well experienced in all branches. Abstainer. Excellent testimonials.—A. DAVIES, The Gardens, Llysidiann Hall, Newbridge-on-Wye.

GARDENER (HEAD WORKING).—Age 36, married; twenty-three years' sound practical experience in every branch of the profession.—HAROLD, Mr. Myatt, Weston Heath, Newport, Salop.

GARDENER (HEAD WORKING).—Middle-aged; has a thorough knowledge of his business in all its branches. Land if required. Six and a half years' good character.—W. B., Longhurst Cottage, Bracknell, Berks.

GARDENER (HEAD WORKING).—Age 40; married, no family. Practical experience in all branches of the profession. Good character and recommendations.—GARDENER, Waltham Place, Maidenhead, Berks.

GARDENER (HEAD WORKING); age 30.—EDWIN BECKETT, Gardener to H. H. Gibbs, Esq., Aldenham House, Elstree, Herts, can highly recommend a young man as above. Well experienced in all branches.

GARDENER (HEAD WORKING).—Age 32; married. Practically experienced in the Cultivation and Forcing of Fruit, Flowers, and Vegetables. Can have three and a half years' good character.—W., Crossbrook Street, Cheshunt, Herts.

GARDENER (HEAD WORKING).—Age 25; thorough practical knowledge of Flower and Kitchen Garden, and all branches. Good references for character and ability from late employer.—THOMAS HARVEY, 15, Tomkinson Street, Bishopfield, Chester.

GARDENER (HEAD WORKING).—Age 35, married, two in family; twenty years' experience in all branches of the profession. Nearly five years in last situation.—JOHN FINLAYSON, Dale Cottages, Farnham Royal, Slough, Bucks.

GARDENER (HEAD WORKING), where more are kept.—Age 37, married, no family; thoroughly practical in all Fruits, and a good Plant Grower. Good character. Counties round about London not objected to.—J. D., School Street, Higher Brinksway, Stockport.

GARDENER (HEAD WORKING), where one or two are kept; married when suited.—W. H. DIVERS, Head Gardener, &c., for J. T. Hopwood, Esq., Ketton Hall, Stamford, would be glad to recommend his Foreman T. Price, to anyone requiring a good all-round Gardener and a first-rate grower of Fruit. Three and a half years' excellent character, twelve years' experience.

GARDENER (HEAD WORKING).—Married, one daughter; twenty years' experience as a first-class grower of Grapes, Melons, Peaches, Orchids, Chrysanthemums; also Forcing Roses, and the general routine of a Kitchen Garden. Wife Lodge Keeper or Poultry. First-class testimonials and certificates from various shows. No single-handed place.—L. W. P., 53, Adys Road, Peckham, S.E.

GARDENER (HEAD WORKING).—Age 40, married; 26 years' experience in Vines, Pines, Peaches, Melons, Cucumbers, and all kinds of Stove and Greenhouse Plants, Orchids, and the General Management of a Garden. First-class references. Late Gardener to C. L., Esq., of Peasmarsh, Sussex, who wishes to recommend him, and to whom references may be made. Please state wages.

GARDENER (HEAD, or good SINGLE-HANDED).—Age 31, married; experienced. Leaving through family going away. Three years' good character.—H. OVER, The Hollies, London Road, Epsifield.

GARDENER (HEAD, or SINGLE-HANDED).—Age 45, married; is a good all-round Gardener of considerable experience; would not object to look after Land. Excellent character from last and former employers.—J. M., 15, Carr's Hill, Balby, Doncaster.

GARDENER, thoroughly practical.—Wants to invest Small Capital in good Florists' Business or Nursery, in Suburbs, where his services would be required.—N., 217, Milkwood Road, Herne Hill, S.E.

GARDENER.—Age 28; single. Can be well recommended by present employer. Had experience in all branches in good establishments. Active and industrious.—E. WARREN, The Gardens, Abington Hall, near Cambridge.

GARDENER; age 34, married.—A GENTLEMAN highly recommends his late Gardener to any Lady or Gentleman requiring a thorough practical trustworthy man.—GARDENER, 8, Nassau Road, St. Ann's Road, Stamford Hill, London, N.

GARDENER (WORKING).—H. G., late Head Gardener to Lady Lester Kaye, is open to engage with any Lady or Gentleman in want of a good practical man as above.—15, Mount Pleasant, Maldon, Essex.

GARDENER (KITCHEN), or thorough good hand outside.—Age 28, married, one child; strong and energetic.—C. ROFFEY, 63, Roden Street, Holloway, N.

GARDENER (SINGLE-HANDED, or otherwise).—Age 23; sixteen years' experience in all branches. Highest references.—J. H. G., 2, Birch Terrace, Orsett, Romford, Essex.

GARDENER (SINGLE-HANDED, or where assistance is given).—Single; seventeen years' practical experience. Twelve years' good character.—J. E. G., 1, Brighton Terrace, Tarring Crossing, Worthing.

GARDENER (SINGLE-HANDED, or otherwise).—Experienced. Nine years' good character. Disengaged. Well recommended. Left through employer's resignation.—G., 6, Albion Street, Halton, Hastings, Sussex.

GARDENER (SINGLE-HANDED, or otherwise).—Age 30, married, no family; good practical experience in all branches; energetic and trustworthy. Eight years' good character.—T. HURST, Schamel, Sittingbourne.

GARDENER (SINGLE-HANDED, or where help is given).—Age 27, married, no family; twelve years' experience in Stove and Greenhouse Plants, Vines, Melons, Cucumbers, Flower and Kitchen Garden. Good character.—J. W., 23, Drysdale Road, Lewisham Road, Lewisham, S.E.

GARDENER (SINGLE, or good SECOND).—Age 22; married, no family; understands Vines, Melons, Greenhouse, and Conservatory. T. tal abstainer. Six months' good character, and good reference.—E. MORLEY, Newdegate, Dorking.

GARDENER (SECOND, or SINGLE-HANDED).—Age 21; seven years' experience Inside and Out. Good reference.—G. PIGG, Mill Road, Royston.

GARDENER (good SECOND, or SINGLE-HANDED).—Age 23; ten years' experience Inside and Out. West End suburbs preferred.—BAKER, Ashford Nursery, Ashford, Middlesex.

GARDENER (good SECOND, or otherwise).—Age 25; experienced in all branches. Good references. E. N., Clare Cottage, Page Street, Mill Hill, N.W.

GARDENER (SECOND), where three or four are kept.—Thoroughly understands Glass and Kitchen Garden. Highly recommended.—WOODHAMS, The Gardens, Ball's Park, Hertford.

GARDENER (SECOND), in the Houses. Age 21; six years' experience in Tomatos, Cucumbers, Stove and Greenhouse Plants. Good references.—100, Chaptman, Boston Spa, Yorkshire.

GARDENER (UNDER), Inside or Out.—Age 21; good experience. Good character from present situation. Total abstainer.—JAS. BURGESS, Oaklands, Crickelewood, N.W.

GARDENER (UNDER), in a Gentleman's establishment.—Age 20; wishes to improve. Highest references from present employers.—W. MASON, Beamhurst Hall, Uxoteter.

GARDENER (UNDER), or COWMAN.—Age 26, single; strong, and willing to make himself generally useful.—W. DAY, Codicote, Welwyn, Herts.

FOREMAN, in the Houses, in a good establishment.—Age 25; has a good knowledge of Stove and Greenhouse Plants; also Early and Late Forcing. Good references.—C. LINK, Everingham Park, York.

FOREMAN; age 28.—Mr. JACQUES wishes to highly recommend C. Bidwell as a thoroughly efficient Plant Foreman. Two and a half years' character.—Boston Road, Hanwell, Middlesex.

FOREMAN, in a good establishment.—Mr. GEORGE MOUNT, The Rose Nurseries, Canterbury, can with confidence recommend a young man (age 25) as above. Has a good knowledge of his profession, and is thoroughly trustworthy.

FOREMAN; age 26.—Mr. CORNFORD wishes to recommend his Foreman to any Gardener requiring an intelligent and trustworthy man. Ten years' experience, two as Foreman.—G. Foreman, The Gardens, Quex Park, Birchington, Kent.

To Nurserymen.

FOREMAN (GENERAL), and PROPAGATOR.—Advertiser, who is filling the above capacity, is open to engagement. Well up in Fruits, Roses, Coniferie, Rhododendrons, and General Routine of the Trade, Wreaths, Crosses, &c. Sixteen years' experience. Satisfactory references as to honesty, sobriety, and ability.—FOREMAN, Dell Nursery, Rock Ferry, Birkenhead.

FOREMAN, or FOREMAN and PROPAGATOR, where Plants and Cut Flowers are grown in quantity for Market.—Twenty years' experience. Can take Management of late Grapes, Cucumbers, and Tomatos.—G. T., Garden Cottage, Brentford Ead.

FOREMAN, or good SECOND in a Nobleman's or Gentleman's Garden.—Has a knowledge of Grapes, Peaches, Melons, &c.; has also had Charge of a good Collection of Specimen Exhibition Stove Plants. Can be well recommended.—HOWELLS, Fox and Hounds, Bankyfelin, near Carmarthen.

PACKER.—Wanted, by the Advertiser, situation as above. Thoroughly experienced, also well up in making Bouquets, Wreaths, Crosses, &c. Good references.—R. H. B., s, Beacon-field Terrace, Perry Hill, Catford, Kent.

HOLLOWAY'S OINTMENT and PILLS.—Rheumatism and Rheumatic Gout are the most dreaded of all diseases, because their victims know that they are safe at no season, and at no age secure. Holloway's Ointment, after formation of the painful parts, gives greater relief than any other application; but it must be diligently used to gain this desirable result. It has been highly commended by rheumatic subjects of all ages and both sexes, for rendering their attacks less frequent and less vigorous, and for repressing the sour perspirations and soothing the nerves. In many cases Holloway's Ointment and Pills have proved the greatest blessings in removing rheumatism and rheumatic gout, which has assailed persons previously and at the prime of life.

THOMAS GREEN & SON, LIMITED,

SMITHFIELD IRONWORKS, LEEDS, AND SURREY WORKS, BLACKFRIARS ROAD, LONDON, S.E.,

HORTICULTURAL ENGINEERS to HER MAJESTY THE QUEEN, call Special Attention to their

PATENT WROUGHT-IRON MUNICIPAL OR ANGULAR CHAMBERED AND TUBULAR HOT-WATER BOILERS,

And others with SHELVES, and Hollow or Ordinary Cast-iron GRATE BARS.

SADDLE BOILERS, With WATERWAY BACKS and WELDED BOILERS, any of which are specially adapted for Heating Greenhouses, Conservatories, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c. They are the neatest, cheapest, most effective, and durable of any extant.

The MUNICIPAL and TUBULAR ones are remarkable for their great heating power, slow combustion, and the length of time the fire will burn without requiring attention.

These Patterns secured the **FIRST and HIGHEST PRIZE a SILVER MEDAL**, at the Royal Horticultural Society's Exhibition, South Kensington, London, June 1, 1881.

— FRONT ELEVATION —

— LONGITUDINAL SECTION —

SECTIONAL PLAN.

The longitudinal section gives a view of the fire-box, water space, flues, &c.

The front elevation shows it set in brickwork, which is necessary for this class of boiler.

The cross section gives a view of the fire-box, water space and V-shaped back.

TESTIMONIALS.

Messrs. THOS. GREEN AND SON, LTD., NORTH STREET, LEEDS.

Re HEATING APPARATUS.

Borough Engineer's Office, Municipal Buildings, Leeds, January 9, 1886.

GENTLEMEN,—I have great pleasure in bearing testimony to the efficiency and satisfactory working of the Hot-water Heating Apparatus you erected in these public buildings. The buildings are four storeys high, and we have a total length of about 23,000 feet of piping in them, varying in size from 1½ in. to 6 in. diameter, with their connections, &c. The several offices and rooms can all be in operation at one time or separately, and the heat regulated by means of the valves to the temperature required, even in the coldest weather. Two of your Patent Municipal Pattern Boilers, No. 4, work the whole of this piping easily, although we have three of them fixed. They are very powerful and economical in the consumption of fuel, and I am pleased to be able to report of them and the apparatus so favourably.

I am, Gentlemen, yours truly, THOS. HEWSON, Borough Engineer.

GENTLEMEN,—The large Municipal Boiler which you sent me last year is doing its work satisfactorily; it is heating 5,000 feet of 4-inch pipe in one of my vineries, and I am quite sure that it has power to work a much greater length, while in cost of fuel it compares favourably with my other Boilers.

I have now five of your Boilers in use, and I cannot speak too well of their heating powers, or their comparatively small consumption of fuel. Yours faithfully, (Signed) G. W. BASHFORD.

AND HUNDREDS OF OTHER REFERENCES CAN BE GIVEN IF REQUIRED.

WATSON and SCULL, 90, Lor Thames Street, London, E.C.

SHARPE'S VICTOR POTATO. CAUTION.

Messrs. CHARLES SHARPE and CO., Sleaford, Lincolnshire, wish to caution buyers of the above POTATO to see that they are supplied with the true variety, as many spurious stocks are offered under the name of Victor, and great dissatisfaction has ensued. The true VICTOR, as sold by Messrs. CHARLES SHARPE & Co., is a medium-sized flatish oval, smooth skinned variety, with very shallow eyes and yellow flesh—extremely early, producing Potatoes fit for use in eight or ten weeks from planting. Large quantities of a later, rough-skinned, round white-fleshed Potato have been sold for it by some houses. To secure the true kind apply either to CHARLES SHARPE & Co., or to a firm supplied direct from them.

CATALOGUES ON APPLICATION.

CHARLES SHARPE AND CO., Seed Growers and Merchants, SLEAFORD, LINCOLNSHIRE.

W. GORDON, IMPORTER OF ORCHIDS from all parts of the world. An immense Stock of recently imported plants compels a Sale of the Established Plants to make room. These have not yet flowered, but are all flowering plants, and must be sold at a great sacrifice. Very valuable varieties are certainly to be obtained, and great bargains. See Public Journals for high prices recently obtained. The special offer affords a paying investment to anyone with glass at command which should not be overlooked. Such plants may never again be offered to the Public and the Trade.

LILIUM AURATUM, 4s., 6s., 8s., and 10s. per dozen, the best that money can buy anywhere. Specially imported ne plus ultra bulbs, 2s. 6d. each. Very liberal allowance to the Trade.

LILIUM ALBUM KRAETZERI, the most lovely white Lily grown—throws seven to ten flowers, which sell in market at 2s. per dozen; beautiful and rare, 1s. each, 10s. per dozen.

LILIUM SPECIOSUM RUBRUM CRUENTUM, the dark form of this lovely Lily, most exquisitely marked, 1s. each, 10s. per dozen.

LILIUM AURATUM PLATYPHYLLUM RUBRO-VITTATUM, crimson, striped with gold; VIRGINALE, pure white, and spotted, with gold band. All these lovely new and distinct forms of Anatum, suitable for show purposes, very fine bulbs, 5s. each.

LILIUM HARRISII, 10s. per dozen; and all other LILIES equally cheap. Banksian Silver Medal awarded August, 1887. JAPANESE NOVELTIES, 80 varieties; IRIS, Tree PEONIES, MAPLES, CAMELLIAS, AZALEAS. Please apply for special offer to W. GORDON, The Nurseries, Aymond Park Road, Twickenham, Middlesex.

CHOICE CACTUS DAILLIAS, pot roots, sound.

MRS. HAWKINS (new yellow), 9d. each; 6s. per dozen. J'AREZII (crimson-scarlet), 9d. each; 6s. per dozen. COCHINEAL (dark velvety-crimson), 9d. each; 6s. per dozen. GLARE OF THE GARDEN, 6d. each; 4s. 6d. per dozen. CONSTANCE and MR. TAIT, 1s. each, pure white. SINGLE DAILLIAS, PARAGON, and WHITE QUEEN, two of the finest for cut flowers, 4s. 6d. per dozen.

DOUBLE DAILLIAS, to name, fine-show varieties; pot roots. The above are very healthy sound pot roots.

Carrriage paid for cash with order. Magnificent new Dwarf Striped PETUNIA SEED. This is without doubt the finest strain possible to grow. The plants commence to bloom 3 in-hes high, and are most attractive; scarcely two flowers are alike. Thousands are sold in Covent Garden Market, and acknowledged by all to be the best they have ever grown. Per packet, 2s. 6d., post-free. CHARLES BURLEY, Nurseries, Brentwood, Essex.

100 Herbaceous and Alpine Plants for 25s.
RICHARD SMITH AND CO.'S selection as above contains a most interesting and valuable assortment of beautiful and Hardy Plants for the Border or Rock-work, which produce flowers and render the garden attractive all through the year. New LIST of sixty-four pages Free.
 RICHARD SMITH AND CO., Nurserymen and Seed Merchants, Worcester.

- 100 CONIFERS, in 50 distinct varieties for 50s.
 - 100 ORNAMENTAL TREES, in 50 distinct varieties, including many variegated golden and purple Acers, &c. for 50s.
 - 100 DECIDUOUS SHRUBS, in 50 distinct varieties for 20s.
 - 100 EVERGREEN SHRUBS, in 50 distinct varieties for 30s.
 - 100 ROSES, in 50 finest varieties, of H.P. and Tea on the Seedling Brier, from the open field for 35s.
- We may state that we have grown Tea on the Seedling Brier in the open field for many years back, proving that they are about as hardy as the H.P., as we have frequently had the latter cut back to the snow line. It is only when the thermometer registers below zero that they require protection.
- 100 HERBACEOUS PLANTS, in 50 fine varieties for 20s.
 - 100 PRIMULAS, in 50 distinct varieties for 50s.
- Catalogue of Names may be had free on application.

Spring, 1888.
NEW WHITE ROUND POTATO,
WEBBER'S "EARLY WHITE BEAUTY." Awarded First-class Certificate, Royal Horticultural Society, September 21, 1887. The many testimonials received from well known authorities speak so well for the excellence of this splendid new white-skinned Potato that a lengthy description is unnecessary; in short, it possesses every good quality. It is of handsome appearance, with shallow eyes, and the superior of the "Beauty of Hebron" both for quality and productiveness, whilst its dwarf habit and extraordinary quickness of maturation make it invaluable for early work. It has been tried on all kinds of soil with most satisfactory results, producing in every case a fine crop entirely free from disease.

TESTIMONIALS.

From Mr. HOPGOOD, Gardener to Sir Julian Goldsmid, Dart, M.P., *Somerhill Park, Tonbridge.*
"I have tried your new Potato, White Beauty. It is first-class, fine flavour, and handsome when put on the table. It must become a great favourite."
From Mr. F. BRIDGER, Gardener to the Right Hon. Lord de l'Isle and Dudley.
"Webber's Early White Beauty Potato has proved the best I ever grew, unrivalled for flavour, colour, and cooking qualities; very productive, haulm about 18 inches high, quick in maturation. I planted the second week in June, and lifted the first week in September a splendid crop, quite equal to those planted two months earlier."
From Mr. C. GOLDSMITH, Kelsey Manor Gardens, Beckenham.
"I have much pleasure to inform you the Early White Beauty Potato you sent me to try has turned out to be a first-rate kind. It is rightly named, and cannot fail to give every satisfaction."
From Mr. EDMUND COLE, Gardener to Earl Spencer, K.G., Althorp, Northampton.

"Having had the opportunity of seeing and testing the qualities of your Early White Beauty Potato from both heavy and light soils, I can say the tubers are perfect in form, and when cooked are very mealy white, and in flavour all that can be desired."
From Mr. CHISHOLM, Gardener to Sir Francis Geary, Ozonhoath, near Tonbridge.
"I have much pleasure in sending you my favourable opinion of your new Potato, more especially as to its good table qualities. My family agree with me that it is the best flavoured variety we have ever tasted. I do not hesitate to predict for it a prosperous future. I will recommend it to my friends, and grow it largely myself during the coming season."
See Testimonials continued next week.

CATALOGUE POST-FREE.

The CHICAGO FLORAL COMPANY (W. G. Hewitt, Manager), Chicago, Illinois, Jan. 23, 1888.

"Two years ago we sent to your firm (also to another celebrated establishment) for Primula seeds. Yours were by far the finest in colour and the largest flowers, many of the single pips larger than a silver dollar, the whites very large and fine."

J. HOLLINGSWORTH, Esq., Mount View, Heathcote, Victoria, Australia, December 1, 1887.

"All the seeds that I have had from you have come out splendid. The Primulas were splendid, and I was told by a competent judge that they were the best he had seen in the colony, and I happened by chance to grow them well. My place is now quite a home of flowers."

SWANLEY, KENT.

WORKS OF AUTHORITY ON BOTANY.

SIR JOSEPH PAXTON'S BOTANICAL DICTIONARY. Comprising the Names, History, and Culture of all Plants known in Britain, together with a full Explanation of Technical Terms. Medium 8vo, cloth, price 25s.

London: BRADBURY, AGNEW, & CO., Bouverie Street, E.C.

VEITCH'S NEW ASTER, DIADEM,

The Most Beautiful and Strikingly Attractive Variety in Cultivation.

This lovely and most desirable new Aster is of dwarf pyramidal habit. For grace and beauty the flowers are quite unique; they are very double, and the two or three outer rows of petals, being pure white, form a charming contrast to the inner petals, which are bright rosy-crimson.

Per Packet, 1s. 6d.

For full descriptions of the above and other Choice Novelties, see SEED CATALOGUE for 1888, forwarded Gratis and Post Free on application.

JAMES VEITCH & SONS,
ROYAL EXOTIC NURSERY, CHELSEA, S.W.

"THE DANIELS" Is the coming POTATO.

A cross between the White Elephant and Magnum Bonum, having the unexcelled qualities of both. Ready to lift same time as White Elephant. An immense cropper, and of splendid table quality. All Potato growers should try it.

Price per peck, 3s. 6d.; per bushel, 12s. 6d.; per sack, 30s.

From Mr. J. ERR, Broom Park, Clebury Mortimer, Oct. 29:—"The seed Potatoes, The Daniels, I bought of you last spring have turned out remarkably well in quantity as well as quality; I had 286 lb. from 7 lb.; not one diseased."

From Mr. E. PITT, Ventnor, I.W.:—"From 2 lb. of your new Potato, The Daniels, I have raised 213 lb., of splendid quality."

A CHANGE OF SEED ALWAYS PAYS.

Before ordering your supply send for Daniels' Illustrated Potato Catalogue, containing valuable hints on the Potato, with descriptions of nearly 200 kinds, and the latest Novelties. Gratis and Post-free to all applicants.

SOME NEGLECTED ROSES.

HYBRID PERPETUALS.

OF course I do not mean that the "H.P.'s," as they are familiarly called, are neglected; they have, on the contrary, taken the lion's share of the rosarian's affections, time, space, and money: but I mean that there are some hybrid perpetuals which are well worthy a place in our gardens, a place they did once occupy, but which the eagerness of exhibiting, and the fashion it sets even to those who are non-exhibitors, have driven off the field; and in mentioning a few of them I may be, I hope, doing a service to those who would fain emulate (however futile the attempts may be) those whose stands they have stood admiringly before at the various Rose shows they have attended.

There are two causes which have led to the rejection of many Roses—want of size, or want of correct form. Of these the former is the most potent; indeed, I am not sure that it is not too large a factor in all cases. It is sometimes said that you cannot have a Rose too large if it is good both in colour and form: I am not at all so sure of this, and I think it would be a fatal day for us if stands of the various colours could be set up with Roses as large as Paul Néron or Antoine Mouton; but be this as it may, it has led to the rejection of Roses which I once remember to have, as I thought, graced many an exhibitor's stand. Then, again, as to shape: a Rose such as A. K. Williams has by some been pronounced to be too formal, and Marie Baumann or Alfred Colomb have been preferred; but if a Rose lacks shape the exhibitor will not tolerate it—will not allow it a place in his box, or, indeed, in his garden; and yet, although he may be quite right to exclude them from the former, he may, unless his whole soul is bound up in the exhibition-tent, give them a place in the latter. Let me, then, bring forward a few which certainly deserve better treatment than they now receive.

Comtesse Cecile de Chabrillant.—This is one of the most exquisitely formed Roses we have; it was

raised by Marest, and sent out in 1859, and if not the only Rose he ever raised, certainly was the only one by which his name is likely to be remembered. It is of a clear satiny-rose, with the petals most beautifully folded, more like the form of a good Persian Ranunculus. It is not very vigorous in growth, although I cannot regard it, as some do, as a moderate grower. The wood is short, but the blooms are freely produced. I remember when we used to look out regularly for the exquisite blooms that good old Mr. Hedge, of Colchester, used to exhibit of it, but now "none so poor as to do it reverence." Very pretty is the verdict, but a great deal too small.

Anna Alexieff.—This Rose, on the other hand, is not of good shape, but it is most vigorous in habit, and an abundant and continuous flowerer. It was raised by Margottin thirty years ago, and ought still to hold its own as a garden Rose for its free habit. It is, however, but rarely seen. Sometimes it creeps in in a provincial show, but as its chief merit cannot be seen there, it is unnoticed. In the garden, and especially as a pillar Rose, it is sure to attract attention.

Eugène Appert.—Well do I remember the sensation Mr. Standish created when he brought up a stand of this flower to the National show held many years ago at Hanover Square Rooms. "Have you seen Standish's new Rose?" was heard on every side, and yet now it is very much relegated to the background. It was raised at Angers, by Tronillard, Lefroy's foreman, and is evidently of the Géant des Batailles race—that race which once reigned supreme; it is of a deep velvety-crimson colour, unlike any other Rose that I know; it is, however, defective in shape, and has, as the "Giant" and most of his family, a tendency to mildew.

Empereur de Maroc, raised, according to Ellwanger, by Ginoiseau, in 1838, and sent out by Eugène Verdier, is another of those attractive high-coloured Roses, which are always sure to please; but the superior character of such Roses as Louis Van Houtte and Reynolds Hole have eclipsed such flowers as this; but I am sure that as a garden Rose it is superior to either of them, it is so very free and rich. This also is apparently of the Géant race, and has one of its failings—the tendency to mildew.

Souvenir de Charles Montault, raised by Moreau-Robert, and sent out in 1862. It has never been an exhibition Rose, but as a garden Rose, bright in colour, very free flowering, and especially good in autumn; very pleasing, and for those who like bright Roses, irrespective of exhibition purposes, it is a desirable Rose.

Boule de Neige, Baronne de Maynard, &c.—Although these Roses—several of which originated with Lacharme—are sometimes classed as hybrid Noisettes yet as the National Rose Society classes them in its catalogue of garden Roses under this class, I follow their line. They are all small—too small ever to be useful to the exhibitor, but very pretty in the garden; they are very free flowering, and although there is some difference between them, yet they bear such a strong family likeness that they may well be classed together. Giving, as they do, a constant supply of very pure white Roses, they ought to be in every garden where space can be found for them.

Souvenir de Dr. Jamain.—This also is a Rose of Lacharme's raising, very distinct in colour—a sort of ruby-claret, and imbricated in form, but too small for exhibition purposes; it is more than probable, however, that this Rose will be superseded by the new English-raised Rose, Sir Rowland Hill, which gained the National Rose Society's Gold Medal, and has been most highly spoken of by all who have seen it; it is almost identical in colour with the Rose now under review, but has that which it lacks, good size.

Anna de Diesbach.—This is also a seedling of Lacharme's, and at one time it was highly thought of, and even now ought to be valued for its vigorous growth, hardness, and fragrance. There is rather a commonplace character about its colour, but notwithstanding this it ought to be more generally grown; it is admirable as a pillar Rose.

Gloire de Rosamène.—This may be regarded, I

think, as having a great deal to do with the brilliant coloured Roses belonging to the H.P. class. Général Jacqueminot is generally considered to have been a seedling from this, and although at times it is hardly double enough—partaking in this respect too much of the character of its parent—yet there are times when it stands out above all the high-coloured Roses; and although forty years and more have elapsed since it was first sent out, it has more than once lately run an extremely close race for the medal for the best Rose in the show. The General has also been the parent, evidently, of many of our high-coloured Roses, so that, if for this reason only, *Gloire de Rosamène* ought to find a place in the rosarian's garden; but as a pillar Rose it is very beautiful, being brilliant in colour and very free flowering.

These are some of the Roses which I think ought not to be driven out of gardens because they are not suitable for exhibition. I know the exhibitor grudges every piece of ground occupied by a non-exhibition Rose, but I contend that there is no reason why the general public, who do not exhibit, should be led away from really beautiful and useful Roses. They are not seen on the exhibition table, and, therefore, "out of sight out of mind" holds good with them as with many other things.

There are, I dare say, others which might be added to this list. Why not, some would say, include Paul Néron? Is it not highly prized in France? Most assuredly it is, and especially in autumn. Two years ago I went to see my old friend Margottin, in September; he had his sitting-room filled with Roses, but only one kind, and that was Paul Néron; he was loud in his praises of it, and said there were none to be compared with it for autumn blooming. Personally I do not like it; its enormous size detracts from its beauty. But in the autumn this is, of course, not so perceptible, and many may like to add it to their collection, or not discard it therefrom. So again some may like Madame Clemence Joigneaux or Baronne Prévost; but I have not desired to overburden Rose lovers but only to suggest a few which have not met, as I think, with the favour they deserve, and have been rejected for others which will be forgotten when those I have named will be gratefully remembered and lovingly cherished, *Wild Rose*.

NEW OR NOTEWORTHY PLANTS.

ANGRÆCUM SANDERIANUM, n. sp.*

This is very near *Angræcum dependens*, Rehb. f. It has an ascending or erect stem with distichous cuneate oblong leaves with an abrupt point at one side. My largest leaf is 4 inches long by $1\frac{1}{4}$ to $\frac{3}{4}$ wide. The peduncle is light brownish-green, more than a span in length. One can scarcely call it fractiflex, though it has some obscure indigitations of the rachis. The tumid base of the pedicelled ovary is very short, plump, scarcely equal to the short triangular bracts. The filiform acute usually ascending spur is three times the length of the stalked ovary. The flower has quite a distinct stamp from that of *Angræcum dependens*, inasmuch as all the floral envelopes are shorter, and the petals and lip rounder with a very short apiculus, whereas in *dependens* the lip is longest and always shows a tendency to be trilobed. The column has two membranous ears to the androclinium and not a vestige of those hairs which are so frequent in *dependens*. The rostellar process is well developed. Anther narrow, apiculate. Of course the flowers are white,

* *Angræcum Sanderianum*, n. sp.—Caule erecto seu ascendente medioeris; foliis cuneato-oblongis apice inaequalibus, altero latere dente proliente; racemo pendulo ad 11-flora bracteis minutis, pulvinaribus basilariibus tumidis, bracteis aequantibus calcaribus filiformibus acutis ascendentibus; sepalis triangulis, tepalis labelloque ellipticis apiculatis; columna circa androclinium bicurva membranacea, ciliata, calvissima; anthera apiculata augusta. Sine dubio ex insulis Comoro ab exc. Humblot missum, ad exc. Sander seri lubentissime dicatum. H. G. Rehb. f.

ovary reddish-green. I suppose it to be an introduction of Monsieur Leon Humblot. The name is intended to commemorate Mr. F. Sander's high merits in populating our collections. H. G. Rehb. f.

CATASETUM TRULLA (Lindl.) MACULATISSIMUM.

This singular variety has well developed fringes on the anterior side of the side lobes of the lip. The petals and lip are covered with brown spots, as is also the anterior part of the sides of the column. It was kindly sent me by Mr. W. Bull. H. G. Rehb. f.

CÆLOGYNE FUSCESCENS, Lindl.

A very pretty *Cœlogyne* apparently exists in some collections, either without a name or under an erroneous one, and a few days ago specimens reached me for identification. The raceme bears about six flowers, of a pale buff tint, the upper sepal keeled and broader than the lateral ones, the petals very narrow, and the lip quite entire. This latter is pale buff, whiter towards the base, with three broad reddish-brown keels from the base to the middle, then much fainter to near the apex. The lateral lobes are broadly margined with sepia-brown, and a few blotches of the same colour inside the margin, the bands curving inwards to join the lateral keels at the base of the front lobe. The variety figured by Lindley in these columns, in 1848 as var. *brunnea*—also well figured in *Botanical Magazine*, t. 5494—differs in having very distinct side lobes; but in his *Folia Orchidacea* the same author mentions a variety "A," which differs in having an entire lip, with which the plant sent appears to be quite identical. I have not been able to find any figure of this entire-lipped form, which seems to be constantly distinguished from the var. *brunnea* by the entire lip. It is an attractive little plant, and a native of the Himalayas. R. A. R.

CYPRIPEDIUM GALATEA, n. hb.

This is one of Mr. Seden's hybrids, just forwarded to me by Messrs. Veitch, but of which unfortunately the origin is unknown; perhaps through the seed having been washed off the pot, or some other accident to which even the most carefully recorded experiments are sometimes liable. It is, however, decidedly of the insigne type, and while possessing all the beauty of that species, there are also a number of important differences from which the other parent must be inferred. The general character is that of *C. insigne*, but the upper sepal is much lighter, almost primrose-coloured, the spots denser and more inclining to light purple-brown, and the broad white margin carried right round the sepal almost to the base; the petals are light purple-brown on their upper half, paler below, blotched with purple-brown for a third of their length on the dark portion, and for half their length on the paler one, all finely ciliate; the lip paler and very indistinctly veined, and the staminode with a somewhat less distinct tooth. I cannot trace these characters to the influence of any distinct species, and probably some hybrid is concerned in the parentage. Mr. Seden is strongly of opinion that *C. Harrisianum* × is one of the parents, which would account for the somewhat varnished appearance of the petals, if not also for the spots on these organs. I thought of *C. vernixium* ×, but this, he says, is too modern. The leaf is very similar to that of these two hybrids—green with somewhat indistinct darker tessellations. I cannot suggest any more likely parentage for the plant. R. A. Rolfe.

CÆLOGYNE GRAMINIFOLIA, Par. and Rehb. f.

Some few years ago a most distinct new *Cœlogyne* was discovered in Moulmein, by Mr. Parish, and was described from dried specimens and an excellent drawing. The matter appears to have rested here for some time; but the other day an unnamed *Cœlogyne*, received from Mr. Mann, and collected in or near Assam, expanded its flowers at Kew; while almost at the same moment came others from Messrs. Veitch for identification. They prove to be the above-named species, now apparently for

the first time flowering in English gardens. It is a most distinct species, and cannot be confounded with any other; the long, very narrow, leathery, and dark green leaves, being extremely characteristic. The peduncles are erect, about 4 inches high, clothed at the base with hard imbricating scales, and bearing

but each terminating in a dark brown line in front. This attractive species belongs to the Erecte section of the genus. A drawing has been prepared for the *Botanical Magazine*. I should have said that Mr. Kent, in forwarding the above-named flowers, added a full description of the plants, which agrees pre-

rudiments of one, the change is so gradual that it becomes a very difficult question where to draw the line, even if one were inclined to do so. *N. canariensis*, a species nearly allied to the above, has a very small trumpet or crown, as also has *N. apodanthus*, and others of that set; while *N. elegans*, a sweet little species from Algiers, and of which we have seen two or three forms one of which has an almost obsolete crown, while in the other two that appendage is so small as hardly to deserve the name. *Calliphurria Hartwegiana*, which has now been included with *Eucharis*, seems to stand in the same relation to that genus as *N. Broussonetii* stands to the average Daffodil. In one of the pits at Kew three bulbs have flowered from a small batch received from Mogador, Morocco, about nine months ago; the first opened about the middle of December, and continued with the succession of the other two until now (February 2). The individual flowers are from three-quarters to 1 inch in diameter, pure white, and extremely sweet-scented, from six to nine in a bunch, with never more than four to five open at once. As before stated, there is but the rudiments of a crown, on which three of the stamens are inserted, much longer than the three inserted in the longish tube. The leaves are rather more than half an inch broad, obtuse pointed, pale glaucous green, and rarely less than 1½ to 2 feet long. The twisting of the leaves of Daffodils has been referred to in your columns more than once, but I have never seen it so marked as in the present plant: they are twice or three times distinctly twisted from east to west. It has been suggested that *N. Broussonetii* may be the result of a cross between a *Narcissus* and some other *Amaryllidaceous* plant belonging to another genus. But if I mistake not this is the only species of *Narcissus* found in Morocco. *D.*

ROSE MADAME GEORGES
BRUANT.

We owe to M. Bruant of Poitiers the opportunity of figuring this highly interesting Rose (fig. 28), of which mention has before been made in these columns, and which is alleged to be the result of a cross between the Japanese *Rosa rugosa* fertilised by the pollen of *Sombreuil*, a Tea variety, with white flowers. The hybrid is stated to be very hardy, with much of the foliage of *rugosa*. The buds are elongated like those of *Niphetos*, and the white semi-double fragrant flowers, when shown before the National Horticultural Society of France, excited much interest, but, having been exhibited not for competition, no award was made to it. We look forward with interest to seeing this novelty, for if a cross has really been effected, there is no telling what surprises may be in store for us.

WEATHER PROGNOSTICS.

USEFUL prognostics of the weather (far more certain than the best weather-glass, or Shepherd of Banbury's observations), by Lord Bacon, the learned Dr. Samuel Clarke, Mr. Derham, &c.

We do not here mean to obtrude the idle arbitrary observations of whimsical people upon our readers. That cloud of popular predictions from the brute world, which, partly the sagacity and partly the credulity of our countrymen have established, we set aside as not flowing from any natural necessary relations that we know of in the things themselves.

First, then, a thick dark sky, lasting for some time, without either sun or rain, always becomes first fair, then foul, *i.e.*, changes to a fair clear sky ere it turn to rain. This the Rev. Mr. Clarke, who kept an exact register of the weather for thirty years, since put into Mr. Derham's hands by his grandson, the learned Dr. Samuel Clarke; this, he says, he scarce ever knew to fail—at least, when the wind was in any of the easterly points; but Mr. Derham has observed the rule to hold good, be the wind where it will, and the cause is obvious: the atmosphere is replete with vapours, which, though sufficient to reflect and intercept the sun's rays from us, yet want density to

FIG. 28.—HYBRID ROSE MADAME GEORGES BRUANT.

two or three flowers. The segments are lanceolate, acute, 1 inch long, and pure white; the sepals are keeled, and broader than the petals. The lip is three-lobed, the front lobes deep yellow, white at the apex; the side lobes white, with oblique sepia-brown veins, and almost suffused with the same colour near their apex. There are three linear undulate-crisped keels running down the centre of the lip, the two outer ones being more distinct than the central one,

closely with the one now flowering at Kew. *R. A. Rolfe.*

NARCISSE BROSSONETII.

Were it not that this large genus shows an unusual amount of variation in the size of the trumpet, &c., we should be inclined to refer this species to its old name of *Aurelia*. From Emperor, however, with its long trumpet, to the present plant with only the

descend; and while the vapours continue in the same state the weather will do so too. Accordingly such weather is generally attended with moderate warmth, and with little or no wind to disturb the vapours, and a heavy atmosphere to sustain them, the barometer being commonly high. But when the cold approaches, and by condensing drives the vapours into clouds or drops, then way is made for the sunbeams till the same vapours, being by further condensation formed into rain, fall down into drops.

2. A change in the warmth of the weather is generally followed by a change in the wind. Thus, the northerly and southerly winds, commonly esteemed the causes of cold and warm weather are really the effects of the cold or warmth of the atmosphere, of which Mr. Derham assures us he had so many confirmations, that he makes no doubt of it. Thus it is common to see a warm southerly wind suddenly changed to the north by the fall of snow or hail, or to see the wind in a cold frosty morning north when the sun has well warmed the earth an air wheel towards the south, and again turn northerly or easterly in the cold evening.

3. Most vegetables expand their flowers and down in sunshiny weather, and towards the evening and against rain, close them again, especially at the beginning of the flowering, when their seeds are tender and sensible. This is visible enough in the down of the Dandelion and other flowers, and eminently in the flowers of Pimpernel, the opening and shutting of which, Gerard observes, are the countryman's weather-wiser, whereby he foretells the weather of the following day. The rule is, if the flowers be close shut up, it betokens rain and foul weather; if spread abroad, the contrary. The stalk of Trefoil, my Lord Bacon observes, swells against rain, and grows more upright; and the like may be observed, though not so sensibly, in the stalks of most other plants. He adds that in the stubble fields there is found a small red flower, called by most country people Winepipe (*Anagallis*), which, opening in a morning is a sure indication of a fair day. That vegetables should be affected by the same causes that affect the weather is very conceivable, if we consider them as so many hygrometers and thermometers, consisting of an infinite number of tracheæ, or air-vessels, by which they have an immediate communication with the air, and partake of its moisture, heat, &c. These tracheæ are very visible in the leaf of the Scabious, Vine, &c. From the "*British Legacy*," 1754.

NEPENTHES NOTES.

EVEN at this dull season of the year the *Nepenthes* at the Royal Botanic Garden, Edinburgh, are very interesting, as some remarkably beautiful pitchers are now being developed in a house devoted to their culture.

A batch of seedlings raised in these gardens, from which *N. edinensis* × × was selected, vary much in growth; the urns, however, are very elegant in contour and brilliant in colour. What a fortune they would have been in a nurseryman's hands; at least half-a-dozen distinct variations might have been certificated. The parents were *N. Rafflesiana* and *N. Chelsoni* ×. The progeny partake of the characteristics of both parents—at present in miniature.

A still later batch, hybrids between *N. Veitchii* and *N. Rafflesiana*, are developing some handsome pitchers, which are showing evidence of distinct novelty. The urns are tankard-shaped, with decided appearance of the brilliant *Rafflesiana* markings on the Veitchian broad margin or peristome. Mr. Lindsay proposes naming the most distinct one after the late Professor Dickson, who took great interest in these *Nepenthes*. What a loss the entire botanical world has sustained in his death! A thorough botanist; a *beau idéal* of what a gentleman should be; one of whom we can indeed safely say, he could not have an enemy!

Amongst the species, *Nepenthes Veitchii*, with a leaf-blade at least 4 inches across, is maturing fine

young pitchers about 7 inches long, a very conspicuous object, with its deep golden collar-like rim—as I have heard remarked, thoroughly Gladstonian in appearance.

In striking contrast we have *N. albo-marginata* var. *villosa* developing pitchers on each leaf, the colouring of which is very prepossessing—dark purple flakes on olive-green pitchers, having a conspicuous velvety-white margin, beneath the polished plum-coloured annulus, the whole plant covered with a delicate violet pubescence—a picture of health and beauty.

N. cincta is also producing some handsome and distinct pitchers, the peculiar corrugated annulus developing a singular undulation of shining crimson finely-ribbed lobes, conspicuous and striking, the peculiar oval orifice reminding one of *N. Lindleyana*, excepting that it has signs of a light-coloured margin partly hidden by the annulus. A curious variation is the extraordinary adjunct in the shape of two spur-like projections over the mouth of the urn, which, as the striation proves, form the finish to the peristome of *N. bicalcarata*. A plant of this now making fine leaves, but showing signs of former ill health, bears one abnormal pitcher, the *fac simile* of the figure of Mr. Le Marchant Moore's *N. Dyak*. [Now recognised as the same as *bicalcarata*. Ed.]

The rim of the urn, whether we call it peristome, annulus, or collar, has an importance as indicative of the different localities to which the various species of *Nepenthes* belong. To instance a few: the two forms from Mahé and Silhouette, *N. Pervillei* and *N. Wardi*; the screw-like processes of the Kina Balu, *N. villosa*, *N. Harryana*, and *N. Edwardsiana*; and the Mount Mulu collars of *N. Veitchii* and *N. lanata*, &c.

Mr. Lindsay has drawn my attention to the affinity of the inverted rims of *N. Hookeriana*, Hort., with *N. ampullaria*, Jack, which reminds me that *N. Hookeriana*, Low, and *N. Rafflesiana*, Jack, have completely changed places, and in gardens are doing duty for one another. *N. Hookeriana*, Hort., with its inverted rim in the way of *N. ampullaria*, is, with this species, a native of Singapore, which accounts for the affinity in the peristome—a fact, as I have before remarked, not unusual in *Nepenthes* history. The chapter of accidents which has led to this calamitous change of nomenclature is due to the following causes:—

1. The unfortunate mislaying or loss of Dr. Jack's carefully prepared drawings of *N. Rafflesiana* sent home in 1820 by the ship *Mary*. The failure of Sir Stamford Raffles to introduce living specimens of this handsome Pitcher-plant into England. The burning of the ship *Fame*, by which many MSS. of both Dr. Jack and Sir Stamford Raffles were lost.

2. *N. Hookeriana*, discovered by Mr. (now Sir Hugh) Low, in Borneo, the early developed pitchers of which were figured in the *Bot. Mag.*, t. 4285, as *N. Rafflesiana*, Jack, together with Dr. Jack's description of the earlier discovered but totally different plant, under the erroneous idea that the two plants were identical.

What an instance we have of the beneficent designs of Nature in the development of the upper or cauline pitchers in several species of *Nepenthes*. The lower pitchers have a rounder, fuller form, holding a considerable quantity of water, for which the earth forms a resting-place, to prevent damage to the leaf by breaking it from the stem; whilst the upper or cauline pitchers take a funnel or trumpet-shape, and consequently hold only as much water as the leaf is able to support without damage, the external aid of the ground being absent. The twisting of the cirrhi is also devised to add strength for this purpose. The two forms of pitcher-development were noticed by Dr. W. Jack in the MSS. left by him on the subject of the discovery of *N. Rafflesiana*, and also by Sir Hugh Low when he described his discovery of *N. Hookeriana*.

I have been observing for the last two months the extraordinary health and vigour of a pitcher of *N. Rafflesiana*, Hort., which has extended its midrib some 2 feet in its endeavours to reach the water in

a tank below the stage on which it is growing, the longest midrib on any other leaf of the plant being less than a foot; the urn is highly coloured, free from insects, and has a wonderful covering of bloom, evidently improved by its near contact with the water, and a great contrast to other pitchers on the same plant.

In my notes I have now particulars of exactly a hundred *Nepenthes*, consisting of thirty-two not yet introduced species and varieties, thirty-six ditto introduced, and thirty-two garden hybrids. I am at present undertaking an interesting study—to give each species its exact geographical position—a task of some difficulty, from the conflicting evidence. *Wm. E. Dixon, Assoc. B. Soc., Edin.*

CITRUS FRUITS.

In the report for 1887 of the College of Agriculture of California, Professor E. W. Hilgard gives some analyses which have recently been determined at the College, of Citrus fruits, which are not only interesting, but most important, as showing the points of difference between the several fruits.

Table showing the Chemical Composition of Citrus Fruits.

Description.	Average weight. Grains.	Percentage Results.							
		Rind.	Pulp.	Seeds.	Juice.	Sugars.		Acid.	
						Cane.	Glu. close.		
<i>Oranges:—</i>									
Mediterranean Sweet	288	33.5	65.1	0.9	?	4.47	1.67	1.10	
Riverside Navel*	...	284	30.0	70.0	...	41.4	5.04	2.10	0.92
St. Michael	...	158	17.3	80.1	2.6	52.6	4.09	1.68	1.01
Malta Blood	...	139	26.3	73.2	...	48.6	5.72	1.81	1.52
<i>Lemons:—</i>									
Lisbons...	...	115	35.7	63.9	0.4	43.4	6.79
Eureka...	...	157	22.4	77.6	...	45.2	7.21
Limes	...	54	15.9	83.4	0.7	56.5	6.86

It will be noted that the Navel and Malta Oranges and Eureka Lemons were found seedless, the largest proportion of seeds being found in the St. Michael Oranges. The Navel shows the highest total sugar and lowest acid of all. It thus would seem, says the Professor, that, apart from its inviting outward appearance, the Riverside Navel Orange owes its place in public favour to three chief points: a high degree of sweetness, with a low degree of acid, and the firmness of flesh which invites it to be actually eaten instead of being "sucked," as one is tempted to do with the softer Oranges.

The Mediterranean Sweet and the St. Michael dispute precedence, according as individual tastes differ in respect to size and flavour; but the St. Michael seems to have a greater firmness of flesh in its favour. The refreshing acidity and peculiar flavour of the Blood Orange place it in a different category from the other three.

The first six columns of the foregoing table, however, furnish material for additional considerations, especially when Oranges are sold by numbers and not by weight. The Mediterranean Sweet shows a slightly heavier weight than the Navel, but the larger proportion of pulp in the latter more than makes up the difference.

The St. Michael shows the highest percentage of pulp of all, notwithstanding the relative abundance of seeds; and hence a given weight of this variety would furnish the largest amount of eatable pulp, while if bought per thousand the light weight of the fruit would leave the consumer materially "short" as compared with the Navel or Mediterranean Sweet.

It was found that there is a true deterioration in Oranges kept beyond the point of proper ripeness

* Sample taken from a plate of fine Oranges which received the first prize for the best budded Orange, and best Orange on exhibition at Riverside Citrus Fair.

that amply justifies the preference of consumers for the freshest fruit.

As regards Lemons the comparison between the Lisbon and Eureka tells strongly in favour of the latter. It is larger, and has a higher percentage of pulp as well as of juice, while at the same time the latter is considerably richer in citric acid. The Limes stand nearly at the same point of acidity as the Lisbon, but show a considerably higher proportion of pulp, as well as of juice than either of the two Lemons, being fully 13 per cent. above the Lisbon in the latter respect.

It is understood by the trade, that Oranges especially, deteriorate materially after a certain period, independently of any actual decay; and in special tests made in this regard last season it was shown that this deterioration manifests itself in diminution of both sugar and acid, as well as in a loss of flavour. The fruit gradually becomes tasteless. *J. T. Willis.*

PINE WOOL CARPETS.

UNDER the name of Pine Wool the fibre of the leaves of the Corsican Pine, *Pinus Laricio*, has been known and used for many years for stuffing cushions, for felting purposes in the manufacture of socks for placing in boots, and similar uses. Pine wool flannel has also had a reputation as a remedy for rheumatic affections, but much of the flannel sold as Pine wool consists of a mixture of animal and Pine wool, or of animal wool altogether, simply steeped in Pine-oil to give it the necessary odour.

Quite recently, however, a new use of Pine wool has come to our notice, and this from the turpentine-producing Pine (*Pinus australis*, Michx.) of America, which is known as the Swamp Pine, or Long-leaved Pine. The tree is described as growing "to a height of 60 to 70 feet, and forming almost the whole growth of the extensive dry and sandy wastes called 'Pine barrens,' which, commencing at Norfolk, Virginia, extend southward for 600 miles through Carolina, Georgia, and Florida, with a width from the coast of 100 miles."

Turpentine is the principal product of these trees, but within the last three years a new industry has been established at Wilmington, N. Carolina, in the preparation of Pine wool, and the conversion of it into carpets and matting. A company has been formed for the exclusive purpose of utilising the "Pine straw," as it is called, which it is stated is "destined to force the Cocoa and Jute matting out of the market." The company owns about 2500 acres of well-wooded land in New Hanover County, about seventeen miles from Wilmington, and it is at a place called Crony that the mills have been erected. The following account has been given of treating the leaves, and the propagation and utilisation of the fibre:—

"The green Pine straw, or leaves, gathered in the surrounding forests, is brought to the mills, where the company purchase it at 15 cents per 100 lb. After having been weighed, the straw is carried into a shed, and is spread upon the floor to be cleaned, and to prevent its becoming heated. An elevator takes the material to the second floor of the building, where it is placed in two iron cylinders set up on end and surrounded by steam-pipes. These extractors are 10 feet deep and about 4 feet wide. In these the Pine leaves are thoroughly strained, the vapour going through pipes into an ordinary distillery worm in an adjoining house. Here it is condensed. The result is Pine-leaf oil, the yield being about half a gallon of oil to 1 ton of straw. The oil is a valuable product, and is destined to take an important part in the Pharmacopoeia. It is very highly antiseptic, possesses the advantage of being useful as well for internal as for external application, and is valuable for many surgical and medicinal purposes. The liquid which is condensed from the vapour with the oil is useful for various purposes in the manufacture of other fabrics.

"After the oil has been extracted, the Pine straw, which has now become a beautiful black, is placed in six large iron vats, 7 feet wide, 8 feet long, and 5 feet

deep, and with a capacity for holding from 3000 lb. to 4000 lb. each. It is here mixed with water and alkali, and thoroughly boiled, the process being necessary to remove the silica which forms the outside covering of the leaf. This is a very difficult operation, requiring great skill and care. The silica which is removed is useful for tanning and other purposes. During all these processes the Pine leaf retains its aroma. The last boiling process continues for twelve hours, after which the straw is soaked for forty-eight hours more, and it is then ready for the machinery for cutting up the leaves. For this purpose the straw is taken from the vats, and while still damp is first put into a 'rubber,' as it is called, which is a machine into which the straw is put in on one side, and from which it comes out on the other a pure fibre of a rich dark brown colour, and of soft texture. During all these processes it has been kept saturated with water, but it is next taken to the wringing and breaking machine, where the water is squeezed out, and the curling process is begun. It is then carried to the carding machine, through which it passes, and hence to the drying machine, where every particle of moisture is evaporated, and thence to the press, where it is put up in bales ready for market. Each bale weighs 225 lb., and they are shipped in cartloads of 50 bales. As an idea of the extent of this trade, it is stated that the stock of fibre kept up amounts to 1000 bales. The mill employs about 30 operatives, and is run by a 50-horse power engine. In the carpet factory the appliances and machinery are similar to those in use in establishments of like nature, the machinery being adapted to the spinning and weaving of this particular fibre. After passing it through a carder and cleaner all the impurities are removed, and the fibre now first assumes the appearance of yarn. It is next wound upon spools, after which it is passed to the spinning-frame, and finally to the twister, where two, three, or four strands are twisted into one, after which it is ready for the loom. To make coloured carpets, the yarn is either dyed or bleached, the yarn being wound into hanks for the purpose. The carpets are made up into rolls, and in various patterns.

"The natural colour of the Pine straw yarn is a rich dark brown, which when bleached becomes a creamy-yellow. Stripes of blue, red, green, and yellow, are woven into the patterns. The matting is made to imitate the finer grades of Cocoa matting so perfectly that were it not for the aromatic odour, which is described as a special quality of the Pine carpet, an expert would find it difficult to tell one from the other. These mats are said to have a great many recommendations, such as warmth, durability, disinfectant or antiseptic properties, and, in consequence of the odour emitted, useful in pulmonary, asthmatic, and catarrhal complaints. They are cheap non-conductors of sound, and are impervious to all insects."

Specimens of these mats are amongst recent additions to the Kew museums. *John R. Jackson.*

TRADE NOTICES.

THE CLOVER AND GRASS CROPS.—Messrs. Hurst & Son, of Houndsditch, recently issued their annual Circular in reference to the above, and from it we learn that from the districts yielding the largest produce come reports of smaller crops than usual of English red Clover and Cow-grass. The quantity of seed saved from those first cut shows a fine colour, chiefly small in grain, but well ripened. The prolonged drought of last summer prevented a strong growth for the second cut, and although the heads of seed filled well upon the whole, yet they were comparatively small in number, that the yield must be below the average. Many fields left for seed had to be fed off late in the autumn, feed for cattle having been so scarce. *Bona fide* large-grained English samples will be certain to command high prices throughout the season, and unless those of foreign

seed rule low, the prices of all home-grown stocks are expected to have an upward tendency. Single-cut Cow-grass has produced a good quantity of very fine quality. Respecting foreign red Clover, reports from the Continent speak generally of an under-average crop. Some good samples are expected to come from Brittany, the North of France, and some districts of Germany; the crop in the south of France is short and of poor quality. Some considerable quantity of large grained sifted foreign red Clover was held over from last season and will be certain to command favour. The American crop is reported to be an average one, and already some consignments have been made to this country, and these show fair quality, although somewhat small in grain. The English crop of white Clover is above the average, and of good quality. France has produced a fair crop. The German crop is larger than usual, and the quality of the grain, as a rule, is good, clean, and well-coloured. Of Alsike, the home crop is a heavy one, and good quality is the rule, prices being now lower than ever known before. The German crop is an average one; and the Canadian yield is reported to be a good average combined with fine quality. Trefoil is a medium crop, and prices open at a low level. The Continental yield is reported below the average. Lucerne shows an under-average crop, but the quality of the seed is fine. Of Sainfoin there is a large crop of English Common, but Giant is very scarce. The French crops of Giant and common are much under the average, and prices this season will rule higher than usual. The French crop of Italian Rye-grass appears to have been much over-estimated, and already the finest upland samples are all taken from the producing districts; a decided advance in price has taken place, and it is expected that later on, at the sowing season, good supplies will be difficult to secure. Following the advance in French seed Irish has become dearer, but there is such a great disparity in quality between the two there should always be a relative difference in price. Care should be exercised in selecting samples. Perennial Rye-grasses are unusually fine in quality, the average natural weights being about 26 lb. to the bushel, indicating strong germinating power. Weights under 24 lb. per bushel will be very foul this season. Natural grasses are found to vary very much in yield and quality. Some varieties, such as Timothy, the Poas, Tall Fescue, and Crested Dogstail are scarce. Cock's-foot is below an average yield, and much of it very poor in quality; on the other hand Hard and Sheep's Fescue and Meadow Fescue are plentiful and good. White Mustard shows a large crop of fine quality; the drought appears to have favoured the Mustard crop on the rich Lincolnshire lands. On the other hand Rape is a short crop of poor quality; fine black samples are already scarce, and command full prices.

MISS SLAYMAKER, the daughter of a tenant in the Centre Avenue, Covent Garden, for forty-three years, has removed her business to 25, Catherine Street, W.C.

THE BULB GARDEN.

LEUCOUM CARPATICUM.

THE Rev. F. Tymons, of Cloghran, Dublin, sent me blooms of this variety of *Leucoum vernum*, on January 25, and my bulbs are beginning to bloom on the 29th, about a week later than the Irish. Mr. Tymons says they are thus early with him in the open garden every year, coming before *L. vernum*, which is only just pushing through the ground. There is some doubt in the minds of many whether this is really a distinct variety, but if the grower of *Leucoums* will carefully observe them at this season of their blooming they will certainly find a difference in flower, bulbs, and habit. The bulbs are most distinct, being more like those of the *Amaryllis* than those of the *Galanthus*, which the ordi-

nary *L. vernum* resembles. The leaf partakes of the same divergence, and the flowers have yellow spots with a beautiful golden hue inside the chalice, and frequently are twin-flowered on one scape. Mr. Tymons has seen three flowers on one stem.

I sent bulbs of *L. carpathicum* to Mr. Burbidge last autumn, and he at once noticed the difference in their character from those of *L. vernum*. This plant will be found fully described in the *Gardeners' Chronicle*, March 15, 1884, p. 341, and I now refer to it as the time is here when *Leucoium vernum* will be in bloom, and many growers may be so fortunate as to discover this excellent variety amongst them. *Wm. Brockbank, Brockhurst, Didsbury.*

CYRTANTHUS LUTESCENS.

During the last year or two we have been made familiar with a species of *Cyrtanthus* which promises to become a really useful garden plant, as it is easily cultivated, flowers freely, and lasts a long while; it is named *C. McKenii*, is a native of Natal and has been cultivated at Kew in quantity lately. A second species, very similar to the above, has recently been added, and is now in flower in the Cape-house at Kew, viz., *C. lutescens*. In general character and habit it resembles *C. McKenii*, the bulb being long-necked, leaves narrow, dark green, scape nearly 1 foot long, bearing three or four flowers which are 2 inches long, funnel-shaped, the segments reflexed, and the colour a soft sulphur-yellow. Herbert, in his *Amaryllidaceae* states that "*C. lutescens* has never been in Europe." It is a native of Natal. The Kew plants were obtained from Messrs. F. & A. Dickson, of Chester.

Generally the *Cyrtanthi* are difficult of culture, the bulbs being more disposed to dwindle and rot than to increase in bulk; but *C. McKenii*, and possibly *C. lutescens* also, will prove an exception. As winter-flowering plants for a cool greenhouse they are both deserving of attention. *W.*

HEMANTHUS NATALENSIS.

This is one of the most useful of African bulbous plants, and certainly the best of the *Hemanthi* for general cultivation. It grows and flowers freely under cultivation, which can be said of only one or two other species of the genus. Treated as we treat the *Hippeastrums*, it makes very strong growth, and develops its large drumstick-like flower-heads once, sometimes twice, annually. There are several strong plants of it now in flower in the T range at Kew, and the bright red colour of the large heads of flower is very attractive. At Kew the plants are potted in a rich loam, the bulb being well buried, and liberal supplies of water with plenty of light and an intermediate temperature are given them during the growing season. When the growth withers water is withheld, and the plants are kept in a dry sunny position till new growth, and along with it the flower-heads appear, when water, &c., are supplied as before. *W.*

BIFEROUS FERNS.

I HAVE forwarded you a sketch of part of a frond of *Polypodium crassifolium*, which is producing a second crop of spores. The frond is an old one and the first crop of spores had been removed in sponging. The small dots are the old sori which have produced no new spores, the larger dots those which have produced the second crop. I have never seen any other Fern do this, and not until this year have I seen *P. crassifolium*; but two large plants in the collection here are fruiting a second time quite freely. *W. C. Kew.* [We do not remember to have seen two crops of spores on one frond before, though it may be well known to Fern cultivators. We were also in doubt as to what heading to give to this paragraph. Should we speak of "perpetual" Ferns like H.P. Roses, or should we make mention of "re-montant" Ferns? At last we bethought ourselves of the *rosaria biferi Pasti*. Ed.] (See fig. p. 29, 173.)

ORCHID NOTES AND GLEANINGS.

CŒLOGYNE LENTIGINOSA.

THIS handsome *Cœlogyne* is now flowering in the Kew collection, the large plant being a very interesting spectacle. Two very distinct varieties appear to have completely grown together, one with bright flowers, the other with pale buff, and as several racemes of each kind are borne, the effect is very pleasing. The markings of the lip and the combination of orange, brown and cream colour, together with the period of flowering and the long time it lasts in perfection, render this species a very desirable one for extended cultivation. It belongs to the erect-flowered section of the genus, and, unlike several others—particularly those of the *ocellata* group—is extremely well marked in its characters. *R. A. R.*

CYPRIPEDIUM MEIRAX.

This is a small kind, a garden hybrid, with a good deal of *C. venustum* in it, but inferior to the latter in all points of attraction. To me it has the appearance of a swarthy dwarf, which ought to have been destroyed when it revealed its character. To the *Cypripedium* hunter this will be rank heresy, but I am not by any means singular in holding the opinion that the *Cypripedium* mania is being overdone, and a lot of positively ugly things are being distributed and cultivated by enthusiasts whose idea of beauty in a flower is warped. *C. Meirax* may now be seen in flower at Kew, and we were surprised to learn that the plant—a small one, too—was worth guineas. Near to it are several pans of *C. venustum*, which is not the handsomest of the genus, but it is not nearly so ugly as its bastard offspring, albeit that the panfuls of plants are considered less valuable than the little swarthy specimen. *W.*

SCENT OF DENDROBIUM ENDOCHARIS.

One wonders if the "fragrance hunters" have given this modest-looking but charming Sedenian hybrid between *D. japonicum* and *D. heterocarpum*, its proper meed of praise! The flowers are of a white or creamy tint, with a pale crimson blotch in the centre of the lip, and has a delightful perfume—not too strong—a soft mixture, in fact, of *Violets* and *Primroses*. *B.*

ANGREECUM HYALOIDES.

Perhaps no genus of Orchids presents a greater diversity in the size of its flowers than does *Angraecum*. This is well shown by two species now flowering at Kew. The one is the marvellous *A. sesquipedale*, with its flowers 5 inches across, and with spurs a foot long, and the other the small *A. hyaloides*, which, with flowers, leaves, and even the basket in which it grows, occupies but 2 or 3 inches of space. It flowers with great freedom, the plant under notice carrying eight spikes with seven to nine flowers on each. The flowers scarcely measure half an inch in diameter, and are almost regular, the sepals, petals, and lip all being ovate, the last only slightly larger. The spur is half an inch in length, and is inflated into a little bag at the base. All the parts are white, and, as the name implies, almost transparent. The prettiness of this little plant makes it well worth the small amount of room it takes up, even apart from the interest attaching to the genus, and as *Reichenbach* observes, this species possesses all the arrangements one would expect to find "in a tip-top *Angraecum*." It comes from Madagascar, and requires a moist temperature.

SARCANTHUS PUGIONIFORMIS.

This Orchid possesses a character in its habit of flowering that I have not seen in any other *Sarcanthus*, but which is common in *Stanhopeas*, *Acinetas*, and in some *Masdevallias*; this is the propensity of the flower-spikes to take a perpendicular, downward direction. Even where the stem lies horizontally and the inflorescence originates from the upper side,

it immediately curls over to take this downward position. The flowers themselves are borne in many-flowered spikes, and individually are small, and in colour green, with a few streaks of dull purple. The plant is of a straggling habit, its slender stems being clothed with long, narrow, fleshy leaves. A plant growing on a piece of Birch stem is now in flower at Kew. *W. B.*

DENDROBIUM SUPERBIENS

is a splendid erect-growing species, the stems upon well-grown specimens attaining a height of from 2 to 3 feet, and from 2 to 3 inches in circumference, bearing thick oblong-acute dark green foliage; the flower-spikes are produced from the top and axils of the pseudobulbs, and these for years continue to produce fresh spikes. The raceme bears from fifteen to twenty-six flowers, which continue in beauty for three months; the colour of the sepals and petals is deep rosy-purple, beautifully reticulated with a darker hue, whilst the margins are bordered with white; the lip is of a warm rosy-purple, the disc being ornamented with five raised lines or keels. Its flowers are produced at all seasons of the year, and in many instances on plants only 6 inches high; and if a number of plants are grown some flowers will be expanded the whole year round. This *Dendrobium* is a plant of easy culture, and one that continues to improve, and lasts for many years, provided it is subjected to a high temperature and moist atmosphere. We grow it in a small span-roofed house, in which there is a central walk, and tables on either side, upon which young plants of *Crotons* are grown; the large plants of the *Dendrobies* are placed on the stages with the *Crotons*, and the small plants are suspended from the roof; and under these conditions *Dendrobiums* and *Crotons* flourish admirably. We use small pans for this *Dendrobe*, the compost being simply peat and sphagnum moss; a liberal supply of water to their roots is absolutely necessary, and, therefore, thorough drainage is of the highest importance. During summer we syringe them twice daily, and they are never shaded. In autumn and winter they are kept rather moist, as at this season some are flowering and others finishing their growths. Temperature at night during winter ranges from 60°–65°, and in summer from 65°–70°; the sun will cause the temperature to rise occasionally to 80° or more on warm days, but this is not injurious to the plants if the houses are properly ventilated, and the atmosphere is well charged with moisture. *B. Williams*, in "*Orchid Album*," t. 312, December, 1887.

CŒLOGYNE ASPERATA.

This is a noble evergreen plant, which, when well grown, attains a height of 2 or more feet: its pseudobulbs are oblong, from 6 to 8 inches high, bearing upon the summit a pair of stalked, lanceolate, plaited, light green leaves. The raceme is a foot or more long, arching; the flowers, which number from twelve to fifteen, are some 2 or 3 inches across, and are arranged on the raceme in a two-ranked fashion; the colour is creamy yellow, the lip being richly marbled with brownish yellow veins, which spring from a rugged bright deep orange-coloured central ridge. The flowers are produced during June and July, and continue in perfection for two or three weeks, if they are kept from damp.

The compost Mr. Woolford (who has charge of the Downside collection) uses for this plant is good fibrous peat and sphagnum moss. The plant is grown in a pot, and the drainage is kept in good open working order, so that nothing stagnant remains about its roots. We have also seen this species grown in a mixture of turfy loam and fibrous peat, and under this treatment it thrives equally well. It is a plant which grows freely, and therefore requires a good-sized pot; it also enjoys a liberal supply of water to its roots during the period of active growth, but after this is completed the quantity should be gradually diminished, until only just sufficient is given to keep the pseudobulbs plump and healthy. When new growths and roots begin to appear, extra water must be given, gradually increasing the quan-

tivity with the strength of the roots and shoots. This plant enjoys strong heat, and should be grown at the warmest end of the East India house, well exposed to the light, but shaded from the hottest rays of the sun. *B. S. Williams*, in *Orchid Album*, t. 311, Dec. 1887.

CATTLEYA ELDERADO SPLENDENS

is an evergreen variety, and resembles the typical plant in its youth. Its short clavate stems are about 6 inches high, and terminate with a solitary, ligulate, deep green leaf; the scape issues from between a long narrow sheath on the top of the pseudobulb, and bears three large flowers; the sepals and petals are of a clear rose colour; the lip is large, having a rich, deep orange-coloured throat, succeeded by a circle of white, followed by a belt of rich violet-purple, which extends to the front and round the margins. The colours in this variety are beautifully contrasted and blended, to produce an effect altogether different and superior to that of the original form. It blooms during the months of September and October, and its flowers continue in perfection for three or four weeks.

As before remarked, this *Cattleya* is found in the low-lying regions near the Rio Negro, in Brazil, where the temperature is high, and consequently, in our treatment of this plant we place it at the warmest part of the *Cattleya* house. Some of the plants we cultivate in Teak-wood baskets suspended from the roof; others we have grown in pots, and they appear to thrive equally well in both positions. There is no doubt that in order to flower them well, they require good exposure to light. We use rough fibrous peat and sphagnum moss for potting; but although all *Cattleyas* thrive in this material, we do not advocate the use of a great quantity of it about their roots; the system of potting should be the same as we have previously advised for *C. Mossia* and others, and the drainage must always be kept free. *B. S. Williams* in the *Orchid Album*, t. 310, December, 1887.

BRUGMANSIAS PLANTED OUT IN A COOL HOUSE.

Assuming that Mr. Freeman's enquiries (p. 23) refer to the above, permit me to supplement the answer given in reply to correspondents, which applied to plants in pots. Most likely the dropping of the flowers was due to cold. The sudden early and severe frosts, amounting to 14°, caught not a few cultivators napping more or less soundly; and as planted-out *Brugmansias* are prone to mount to the glass, there are few other inmates of the greenhouse more exposed to sudden chills, or that are more suddenly punished through depressions of temperature.

The sub-hardy growth of *Brugmansia* in the open air in summer is apt to deceive cultivators as to the amount of cold they will endure with impunity under glass. There is also a very general tendency to over-estimate the temperature of houses. Not seldom throughout the summer, and almost as a rule in the late autumn, or early winter, the temperature of cool houses is far lower than that in the open air throughout the summer. This arises from a variety of causes, chiefly from through ventilation and proximity to the glass. Many of the sudden and apparently inexplicable checks and accidents that occur to plants under glass in the late autumn, originate from these two simple but very potent causes.

Apart, however, from these, the temperature of cool-houses is mostly too low, as well as too irregular for the successful blooming of *Brugmansias* so late in the season. Though the mere exclusion of frost suffices for the preservation of the life of *Brugmansias* and many other semi-tender plants throughout the winter, such low temperatures are wholly inadequate to sustain free growth or develop perfect flowers. Doubtless, too, the paucity of light has something to do with the dropping of the bloom in the later autumn and winter months. Such fine trumpets as those of *Brugmansia suaveolens* probably need considerable intensity of light for their full expansion. Heat, however, is the most important factor, as the growth of *Brugmansias* in stoves or intermediate houses in winter has proved. There is

another curious characteristic in relation to the flowers of *Brugmansias* in cool temperatures and under semi-obscur conditions—the blooms that do open are far more persistent under such circumstances. For example, blooms of *Brugmansia suaveolens* at midsummer seldom remain fully expanded more than six or, at the most, twelve hours. Blooms expanded in November or December will keep open eighteen, twenty-four, and occasionally thirty-six hours. Similar differences of durability may be noted in the cut blooms, though in neither case do the cut flowers last so long when cut as on the plants. Neither is the odour so full in winter bloom. The flowers, in a word, seem to possess less vitality, and gain in persistency what they lose in vital energy or force—a result hardly to be anticipated. But in all this it must be borne in mind that there are *Brugmansias* and *Brugmansias*, and that striking differences—contrasts, in fact—exist between the two typical species named by Mr. Freeman; *B. sanguinea* is altogether hardier than *B. suaveolens*, the flower forming more of a tube than a trumpet. It is also without scent, and is more of a winter and early spring than a summer bloomer. These differences account for the differences noted in the present state of the two plants by your correspondent,

FIG. 29.—POLYPODIUM CRASSIFOLIUM (SEE P. 172): TWO CROPS OF SPORES ON ONE FROND.

and suggests somewhat different treatment. Like Mr. Freeman, we have these two species of *Brugmansias* growing side by side in a very cool house, from which only the frost is excluded. Both are giants in their way, and we have had as many as 2000 blooms open at once on our *B. suaveolens*, filling the entire house and garden with incomparable fragrance, and occasionally emitting light in the dark.

As a rule this plant blossoms three times in the summer, with a few stray flowers through October and sometimes up to Christmas. It is then spurred closely back to the old wood like a Grape Vine, and seldom breaks again till the end of April. *B. sanguinea*, on the contrary, is now in full growth and blossom, and will continue so till the middle or end of May. Then it in its turn will be spurred in, and allowed to break in as low a temperature as the season and a through draught can command. It breaks strong, grows on finely, and flowers through the autumn, winter, and early spring, as already described. Of course there are many other ways of cultivating *Brugmansias*, but as ours seem grown under very similar conditions to Mr. Freeman's, and the above treatment has been successful for twenty or more years, it is hoped it may be of some use to your correspondent, and others who grow large planted-out *Brugmansias* in cool houses.

The soil you recommend will doubtless grow *Brugmansias* well, but being gross rooters I prefer rough turfy loam with a dash of rotten dung, and a

sprinkling of crushed bones or charcoal, or anything else. In such compost, a thorough drainage, and sewage only, to quench their thirst when in vigorous growth or full bloom, there will be little likelihood of such mishaps as bud or bloom dropping unless these, as I have surmised, are pinched off by cold. *D. T. Fish*.

GARDENING AND TREE PLANTING AT KEISS.

The seat of Francis Tress Barry, Esq., is situated in the county of Caithness, about 8 miles from the town of Wick, and 600 miles north of London as the crow flies. The Castle here is a noble pile of baronial architecture, and from its situation has a commanding appearance, especially seaward, and its internal arrangements and decorations are in keeping with its exterior. The northern portion of Caithness may be described as an undulating plain, and mostly devoid of trees; this is accounted for by the heavy gales of wind that are so prevalent in these parts, but Caithness is by no means a poor county—its agricultural products are greater than some others of the more southern shires. My principal object is to draw attention to what I saw at Keiss, and to what can be done effectively by simple means. Mr. Barry, after he acquired the property of Keiss some years ago, saw the difficulty of getting trees and shrubs to grow, on account of the wind from the sea, which is so detrimental to their growth, and took measures accordingly.

Keiss Castle is entered from the high road leading from Wick to John o' Groat's (the Land's End of Scotland) by a handsome gate and a neat lodge; the approach road is 16 feet wide, and winds in gentle curves some 400 yards up to the Castle; on each side of this road is a margin of turf 7 feet broad; and as purple Heath is very abundant in this district, Mr. Barry conceived the idea of placing a border of this purple Heath, 6 feet broad, at the back of the turf edging. Accordingly a selection was made of the best Heath in the district, which was lifted in squares 15 inches broad and 4 inches thick and laid closely together in its new position, where it has grown into one dense growth. At the time of my visit last August the Heath border was in full bloom, and it must be said that the effect was very beautiful, and well deserving of imitation. Mr. Monro, the gardener, takes much interest in those Heath beds, and endeavours to keep them neat and tidy, as well as everything else which he has under his charge.

The kitchen garden, which lies to the north-east of the Castle, and consists of a piece of ground 2 acres in extent, is surrounded by a substantial wall of stone. Vegetables of all sorts, and bush fruits do well, but Apples and Pears are a precarious crop; still, at the Apple Congress held in Edinburgh two years ago some fair specimens of the former were exhibited. Plums, as a rule, do well in the North.

The flower garden is placed to the south of the kitchen garden, and contains but little of the ordinary bedding out, but spaces for lawn-tennis and bowls, together with grassy terraces, are extensive, and well kept. From this garden some of the views are grand, and that looking seaward is boundless, while to the south the view takes in the whole of Sinclair's Bay, with Achergill Castle on the verge of the seaward cliff. This was long the residence of the late Sir George Dunbar, who in his day did much for horticulture and agriculture in those parts.

Barrock, once the residence of the late Lady Sinclair, lies about 6 miles south-west from Keiss, and has the advantage (as regards the feasibility of growing trees) of being 4 miles distant from the sea. In this quarter numbers of species of Orchises are found; and the pretty little *Primula scotica* grows very abundantly in the meadows. The deceased lady, with praiseworthy perseverance, planted everything she thought would grow, to form shelter screens. The finer sorts of trees were planted by her behind these, and now there are found good sized plantations about the place in which are many trees of large size. The late Mr. Sinclair, of Forsa, near

Thurso, affords another example of what intelligence and perseverance can accomplish in the matter of improving a district by means of arboreal vegetation. Should the tourist or botanist think of visiting this interesting district, the months of July or August should be chosen for doing so, the long days of the northern part of Britain constituting one of the greatest charms. The sun rises so early and sets so late, that its gleams continue on till midnight, and mingle with the returning light in the morning, so that it may be said there is hardly any night. *John Downie.*

FLORISTS' FLOWERS.

GREENHOUSE PLANTS: THE CINERARIA.

My plants during December and January this year greatly suffered from attacks of mildew, and repeated dustings with flowers of sulphur were necessary to destroy it. For the greenfly, an ever-present pest, I fumigate the houses about once a month. My specimen plants are now in 8-inch pots well exposed to the light. The large outer leaves have been tied down to the rims to allow of the more free development of the centre growths; these in their turn should be tied out, to form a dwarf compact head of bloom.

THE CHRYSANTHEMUM.

Specimen plants should now be growing. It is of course sternly insisted by the framers of schedules that specimen plants should have but one stem, and that the stem should be seen distinctly above the mould in the pot. The experienced exhibitor selects his plants of the large-flowered varieties in November from the plants that have produced his large single blooms. Only those that produce a number of growths on the stem will do; these are shaken out of their pots, and repotted in good soil. If placed on a shelf in any heated house or in the greenhouse they soon grow freely. They are potted in the first place in 7-inch pots, next into 9-inch, and lastly into 11-inch, the size usually allowed by the terms of the schedule. All through the winter and early spring months a cool greenhouse temperature is most suitable. Exposure to frost would check the growth of the plants; but a heated atmosphere, except so much as is required to keep out the frost, would cause a weak growth, and might force the plants into flower prematurely. Pompons produce the best plants from cuttings put in during the month of December, or late in November. They form roots if placed on a shelf in the greenhouse; but they must be grown on very freely after roots have been formed. Each cutting should be put singly in the centre of a small pot—the plants when rooted to be potted on into 5, 7, and 9-inch pots as they require it. The compound in which they are grown must be good loam well enriched with decayed stable manure; and a 10-inch potful of bone-dust to a large barrow-load of the soil. If bone-dust cannot be obtained, pounded oyster shells is good to mix with the soil; and I used shells for drainage. The cuttings ought to be put in now for all purposes; and they form roots most freely in a gentle hotbed. Dip the cuttings in soft-soapy water before planting them in the pots, as a preventative—greenfly may be on them unobserved. The whole stock of potting soil should be prepared now. *J. Douglas*

PICOTEE LIGHT SCARLET-EDGED "NELLIE."

This was one of the late Mr. George Rudd's flowers, and it was sent out in 1882. It was a little disappointing at first, as it lacked refinement; but this was probably owing to the fact that the plants were overgrown. But for two years past it has been finely shown at Oxford by Mr. Martin Rowan, of Clapham, and in its best form, and was the admiration of all who saw it. Mr. Rowan appears to be pre-eminently successful in cultivating it, and in a communication from him, which appears in the recently published report for 1887 of the Carnation

and Picotee Union, he remarks that the light scarlet-edged Picotees were shown in fine form at Oxford, Favourite and Cynthia being mentioned in particular on account of their excellence, and "to them Nellie had to sustain the severest competition for supremacy in her class she has yet had to meet. The interest in the latter variety seems to increase with each season, and some little discussion has lately arisen as to its merits relatively with Favourite. The conditions of complete rivalry between them are wanting, inasmuch as Nellie is naturally a later flower. Nellie is a gem, only late in blooming. This needs to be borne in mind, for though I have, each season, had some blooms of Nellie at about the same time as other sorts, it has been the later ones only which have shown the full refinement of which the flower is capable. The truth is, we are fortunate to possess in Favourite and Nellie two successional varieties of high-class quality, and both should be grown." Favourite is a comparatively recent introduction, and though raised at Thame some few years since, was unknown to the general cultivator until brought by Mr. Thomas Anstiss, of Brill, to the exhibition of the National Carnation and Picotee Society, at South Kensington, in July, 1884, showing it in grand form. It is now foremost at all early exhibitions. It has a pure white ground, a lovely light salmon-rose edge; and the petals are stout and of the finest form. It is one of those varieties which can be depended upon; and it is more likely to carry off the premier prize than any Picotee I am acquainted with. But no one appears to be able to produce Nellie in the beautiful form in which Mr. Rowan gets it at Clapham. *R. D.*

CULTURAL MEMORANDA.

ARDISIA CRENULATA.

SMALL plants of this, covered with berries, are at all times effectively decorative. Seed sown now in a pan of sandy soil, watered, placed on a shelf in a stove or Cucumber-house, and covered with a square of glass, will in due time germinate. The seedlings, when large enough, should be pricked out in a pan at 2 inches apart, and after watering be put again into heat near the glass. The plants should be potted singly before they get crowded in the pan, shifting them when they require it, and continuing to grow them on in heat. During the summer season they may be well grown in a warm pit or frame, when they should be afforded a little more fresh air than they would get in the stove. A mixture of light loam and peat in equal parts, with a sprinkling of sand added, should be used in potting off the plants.

CRONONS.

If the tops of any of the varieties of this plant which the cultivator is desirous of increasing be taken off with a couple of joints of growth and inserted in 3-inch pots filled with sandy soil, and then plunged in a hotbed or propagating pit, watered, and be kept close, they will soon take root, and with proper attention afterwards in the way of pinching, and shifting them into larger pots before the roots get matted in the cutting-pots, they will be of good service as decorative plants before the growing season is over. A compost consisting of half peat and light sandy loam, and a little sand added, will be suitable for these plants.

BORONIA MEGASTIGMA.

This hard-wooded greenhouse plant is not so much grown as it deserves to be. It is of very slender habit and delicate foliage, with erect virgate glabrous branches. The sub-globose campanulate flowers are solitary and freely produced from the axils of the leaves, towards the top of the branches. They are of a beautiful lemon yellow inside, while the outside is of a dark brownish-purple, and are deliciously fragrant. The plant is quite as easily grown as a Heath or an Azalea is, and, like them, should be potted

firmly in fibry peat, giving sufficient silver-sand to render it somewhat porous. The plants will do very well in a cold frame or pit during the summer and early autumn months; afterwards putting them into a heated pit or greenhouse where a night temperature of from 45° to 50° can be maintained, with 5° higher by day, with fire-heat, running up 10° or 15° higher by sun-heat, air being given. Extra care should be exercised in the matter of giving water at the roots. When the condition of the soil indicates dryness give sufficient soft water to thoroughly moisten the ball of earth and roots, afterwards allowing the soil to again become moderately dry before repeating the application. The flowers which are discernible in the autumn, do not open until the spring, when the flowers of a small plant will fill the atmosphere of a large-sized house with their perfume.

AGAVE AMERICANA ACUTEO-VARIEGATA.

Plants of this handsome American Aloe growing in pots ranging from 3 to 6 inches in diameter are of much decorative value when associated with other plants, the bluish-green of the fleshy leaves, which have an edging of creamy-yellow, being very remarkable. Larger plants grown in pots and tubs are frequently seen to advantage stood at intervals on terraces, lawns, and other parts of country gardens. This Agave is easily increased by potting up the suckers or offsets which are produced from the base, using a light sandy loam, with a little leaf-soil added, and growing them on in any light place out of the reach of frost or excessive damp.

ACACIA ARMATA AND A. DRUMMONDII.

This free-flowering, easily managed spring-flowering plant may be had in flower during the winter months by gently forcing the plants. Cuttings of the young growths taken off now and inserted in sandy soil round the edge of small pots, watered, and put into heat, will soon root. They should then be potted singly into small 60's in a mixture of fine sandy loam and leaf-mould—about four parts of the former to one of the latter—and be put back in heat and watered. As soon as the roots have taken to the soil pinch the shoots to make them branch, afterwards putting the plants on a shelf near the glass in a greenhouse or where the night temperature is not likely to fall much below 50°. Give water at the roots when necessary, and give more pot-room before the roots get matted, using the loam in a rougher state at each subsequent shift. *A. Drummondii*, having long yellow flowers, is also an excellent variety, and equally easy of cultivation.

WINTER FLOWERING CARNATIONS.

The present is a good time to take off the desired number of cuttings of winter flowering Carnations. The young side shoots slipped off when about 2 inches long and inserted in 4½ inch pots, previously crocked and filled with light sandy mould, plunged in a hotbed, watered and kept close, will soon take root. They should then be potted singly into small pots, put back in heat for a short time to establish themselves in the pots, when they should be shifted into a less warm structure, afterwards attending to the plants in the way of giving water at the roots, keeping them free from the attacks of aphids, and shifting them into larger pots as they require room at the roots, using a compost consisting of four parts good loam and one of sifted old hotbed manure, with a dash of sharp sand added. Support the plants and harden them off in due time. This must be done gradually, advancing with the approach of fine weather and the progress made by the plants. *H. W. Ward.*

PLANTS AND THEIR CULTURE.

CRINOMS, HIPPEASTRUMS, AND HYMENOCALLIS.—The stock of these should now be looked over, as many plants will be showing signs of growth. It may not be necessary to repot all the stock—indeed, if they are in tolerably large pots, with the soil and drainage in good condition, it is quite unnecessary. A top-dressing of some concentrated fertiliser, with plenty of water during the growing season, will be all that is required; but in the case of small bulbs, which it is desired to grow on, potting would be advantageous. A good yellow loam with a dash of silver-sand, bone-meal, and charcoal will suit them

well. Crinums are a showy family of plants, and not so much cultivated as their merits would warrant; many of them are stately plants, producing gorgeous heads of flowers, usually deliciously scented—they are of various degrees of hardness. C. Powellii is quite hardy, and C. Moorei, C. Macowani, and C. capense are nearly so; while C. Kirkii, C. augustum, and C. amabilis are stove species. Those nearly hardy species make excellent subjects for conservatory decoration, especially if they can be planted out. Of the *Hymenocallis*, *macrostephana* (a stove species) is by far the best. There are now many beautiful hybrids of *Hippeastrums* or *Amaryllis*; but of the original kinds, *Ackermannii*, *reticulatum*, and *vittata*, are well worth growing.

Newly Potted Plants.—Avoid giving much water with the watering-pot; endeavour rather to keep the soil moist by repeated dampings. Syringing the plants (when practicable, as in the case of stove plants or most soft-wooded subjects), pots, stages, and indeed every available place, should be damped. Attention to this matter will prevent the soil from becoming dry. If, at the time of potting, the soil was in proper condition as regards moisture, and the damping, &c., carried out as advised, the plants seldom require any other watering until the roots get to the sides of the pots, by which time they will have a good hold of the new soil, and may then be watered in the usual way. Stove plants which have been recently potted are better kept in a temperature slightly higher—70° at night will be quite high enough for this month, but 85° to even 90° in the day when raised by sun-heat will do no harm.

Dipladenias and Ixoras.—Although these differ widely in general appearance, their cultivation is nearly identical. They both require a high temperature more or less all the year round, even while resting, and the roots of *Dipladenias* soon perish when kept in a low temperature, 60° being quite low enough, except in the case of *D. boliviensis*, which seems to be hardier than any of the others; but both *Dipladenias* and *Ixoras* require abundance of heat and moisture during the growing season—75° at night, with a rise of 10° or 15° with sun-heat in the day; under this treatment they grow very rapidly. *Dipladenias* which have been resting should now have all weak points and the immature parts of their shoots cut out, at the same time taking them off their trellises; and if it be considered necessary repot them, use the best fibrous peat, with sufficient rough silver-sand to ensure free passage to water; pot firmly, and see that the drainage is made perfect, as they are very impatient of an excess of water about the roots. They are much benefited by being stoved or half plunged in tan or cocoa-nut fibre refuse, through which run some hot-water pipes. In such a position very little water will be needed, and to protect them from becoming waterlogged it is advisable to stand them on something, such as a seed-pao, with its bottom nearly all knocked out, which answers very well. The plants will break all the better if the shoots are all laid horizontally around the rim of the pot; or, better, if they can be laid loosely on the top of the plunging material, tying them up to their trellises immediately they break. If they are trained to the rafters of the house, 18 inches from the glass should be allowed, as when they are placed too near the glass they suffer from the great fluctuations in the temperature in such places. *Ixoras* should be similarly treated as regards soil and temperature, but of course no trellis is required; and in pruning, cut them hard back, reducing them to the desired shape or size.

Conservatory Climbers.—These will now be making a move, and in many cases they have a comparatively small root-run. The soil at the end of the season will pretty well have been exhausted, and in such cases all those which have been pruned back should have as much of the old soil removed as can conveniently be done without injury to the roots. The remainder gently pricked up, and a top-dressing of good sound material put on, either peat or loam, according to the requirements, giving a good soaking of water when finished. In many cases, climbing plants, play a most important part in the embellishment of the conservatory, and with occasional plants brought in while in flower a very good effect can be made. But, be that as it may, a good selection of climbers is essential to the proper furnishing of any conservatory. I append a list of plants which are well suited for covering the roof or other large spaces, and which are such as would mount up to the higher parts of the house. Of *Bignonias*, *Cherere*, *speciosa*, and *Chamberlaynii*; *Tecoma capensis* and *jasminoides*; *Kennedya*, *rubi-*

cunda, *Comptoniana*, and the beautiful *Marryatta*; *Tacsonias insignis*, *Van Volxemii*, and *exoniensis*; *Passifloras kermesina*, *Ilahnii*, and *coccinea*; *Bougainvillea glabra*, and *Senecio macroglossus*, with its Ivy-like leaves and yellow *Marguerite*-like flowers, which are freely produced in early spring. Those are suitable for a conservatory, where the temperature is kept about 45° at night in winter. For a cooler house, or where frost is scarcely excluded, the following are suitable:—*Bignonia capreolata*, *Stauntonia latifolia*, *Akebia quinata*, *Lardizabala biternata*, *Mandevilla suaveolens*, *Passifloras corulea* and *Constance Elliotti*, *Physianthus albens* and *Clematis indivisa lobata*. The above is a select selection of strong-growing, free-flowering climbers, and will in many cases be ample, as well as variety enough to furnish the positions indicated.

Zonals.—Any of these that have been flowering during the winter may be cut down, using the tops of the shoots as cuttings, either for growing on for next winter or for flowering earlier. Select the stouter cuttings, about 6 inches in length, with as many leaves attached as possible; and it is best to put them singly into small pots—thumbs answer very well. As a compost light loam, with a pinch of sand at the base of the cutting, answers very well. Stand the cutting-pots where a temperature of about 60° can be afforded them, where rooting will take place in about three weeks. They may then be potted into 60's and gradually hardened off. This is a good time to put in cuttings of show and fancy *Pelargoniums*—the treatment afforded zonals suiting them equally, but they take a little longer to form roots. *F. Ross, Pendell Court.*

THE HARDY FRUIT GARDEN.

PROTECTING APRICOT TREES.—Since writing last, a very low temperature has been experienced, the thermometer showing 17° of frost on one occasion, which, although it has checked the swelling of the buds in general, was of such severity that protection had to be given, the buds being too far advanced to be left unprotected any longer. But now that a change to milder weather has taken place, the trees must be fully exposed night and day, and the curtains only used when frosts threaten.

Peaches and Nectarines.—The pruning and nailing of these should now be done. As regards pruning, if the trees of these received proper attention last year in the way of disbudding, and the removal of gross and useless wood in the autumn, but little will remain to be done now; but should there be still a surplus of young wood, the same should be thinned out, leaving that which is best placed and best furnished with fruit buds, so that when nailed in, the young wood will be about 6 inches apart. Leave short shoots of their full length, but any that are strong had better be shortened back half-way, taking care to cut to a wood-bud. Assuming that the trees were unnailed from the wall before being pruned, and all the old nails and shreds removed, the sound nails, after being taken from the wall, should be placed on an old shovel or something of that description, and burnt over a fire. After cooling somewhat they may be put into linsed oil, which will in a great measure prevent them rusting. When nailing use narrow shreds, and no more of these than are necessary to fasten the trees to the wall, leaving the shreds sufficiently loose that the wood may have ample room to swell. For fastening the main branches use tar twine with something soft placed between the same and the branch, to prevent injury to the bark, and which is preferable to using wide shreds, which only form a refuge for insects, and from which no amount of syringing can dislodge them. Should the trees be infested with scale dress them with the following mixture:—Take a 60-sized flower-pot of soot, one ditto of sulphur, one ditto of clay, and half the same sized pot of soft-soap. Mix these ingredients well together in a bucket, and add sufficient water till the whole is of the consistency of paint, when it may be applied with a brush. After the nailing is finished the temporary copings and the poles for stretching the curtains may be placed in position, so that when protection is needed there will be nothing else to do besides the fixing of the curtains. *A. Ward, Stoke Edith Gardens, Hereford.*

FRUITS UNDER GLASS.

VINES.—Pot Vines swelling their fruit must receive abundance of weak manure-water; and if the pots are not plunged in a leaf-bed this can scarcely be overdone. Attend to the stopping of shoots—two or three leaves should be left beyond the bunch; pinch all lateral shoots at one leaf, and any additional growth should be pinched off as it appears. When Hamburgs and free setting sorts come into bloom, let the temperature range from 65° to 70°. Should the weather be dull and sunless, the pollen may be dispersed by a Pampas plume being gently drawn over the bunches. If the ventilation is so arranged at the front of the house to allow the outside air to pass through, amongst or over the hot-water pipes, a little chink of air should be left on most nights, but be careful not to cause a cold draught, by opening the top ventilators at the same time, or the object in view will be defeated and serious injury will result. Vines which are breaking regularly may have the temperature advanced 5°; when two or more shoots issue from one bud, remove the weakest, and as soon as the bunches can be discerned, a gradual rise of temperature should take place until 70° be reached by the time the Vines come into bloom. Muscats are better by being kept 5° higher than that recommended. Remove all the bunches from a shoot except one, as soon as it can be seen which are likely to be the most compact and shapely. In the case of free-setting kinds, the sooner the bunches can be thinned after they are set the better, but with shy setters this is better deferred until it can be seen which berries will swell and which will not. Another house may now be started to succeed the others. The temperature for starting may now be from 50° to 55°, according to the state of the weather; if stormy, let the lower reading be the rule. Syringe the canes morning and afternoon with water at about 70°. As soon as the Vines burst their buds discontinue the syringe, and damp with a can and rose. Avoid throwing water on the hot-water pipes, and filling the house with steam. Proceed with the pruning of all Vines yet not done, and let the wounds be dressed as soon as dry with styptic, to prevent injury from bleeding. If not already done, remove all Grapes hanging on the Vines; this can be done with a portion of the wood which can be placed in bottles of water, and kept in a dry room. Start Viole-eyes in a gentle bottom-heat, and let the atmosphere of the house range from 50° to 55°, maintaining a moist atmosphere by frequent syringing with tepid water. *Wm. M. Baillie, Luton Hoo.*

THE KITCHEN GARDEN.

FORCING-PITS AND FRAMES.—Enough fermenting material should now be prepared and made into hot-beds when ready, in order that all Potatoes intended for forcing may be planted before the end of the month, and that more seed of Carrots and Turnips may be sown; the Potatoes should have been started in boxes as advised for previous plantings.

It will be advisable during mild weather to have the herb border thoroughly cleaned, or a fresh one planted if it be thought necessary, before other work demands attention. This part of the kitchen garden, which ought to have special attention, is too often found in a very untidy state, or what is equally as bad, no systematic arrangement is attempted, but the herbs are grown in odd corners, causing much loss of time in collecting supplies. If it be decided to plant a new border of herbs, choose a piece of ground that is easily accessible, and which has been well manured and deeply dug; the clumps of Thyme, Savory, Marjoram, Tarragon, Sage, Mint, Chives, Sorrel, &c., should then be divided and replanted very firmly. Mint is sometimes difficult to grow successfully in dry sandy soils, and in such places it should be planted by itself in the coolest and dampest situation possible; any pieces remaining after sufficient have been planted should be laid-in by the heels in a separate place, for use until the others are established. Space should be reserved for Shallots, Garlic, Parsley, Chervil, Marjoram, Basil, &c., until the time comes for planting and sowing them. Continue to cover up more Seakale and Rhubarb whenever required, before the present supply gets exhausted. The latest Mushroom beds outside should now be made up as soon as possible, choosing a place behind a north wall, or some similar cool spot. *W. H. Diers, Kelton Hall.*

Advertisers are specially requested to note, that, under no circumstances whatever, can any particular position in the paper be guaranteed for advertisements occupying less space than an entire column.

SUBSCRIBERS TO

THE GARDENERS' CHRONICLE who experience any difficulty in obtaining their Copies regularly, are particularly requested to communicate with the Publisher (in cases of delay in the delivery by post, the cover should be forwarded with complaint).

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

MONDAY,	FEB. 13—	Chambre Syndicale of Ghent.
TUESDAY,	FEB. 14—	Royal Horticultural Society; Scientific, Fruit, and Floral Committees; and Annual General Meeting.
THURSDAY,	FEB. 16—	Linnean Society.

SALES.

MONDAY,	FEB. 13—	Nursery Stock (First Portion), at Todman's Nursery, Eltham, by Messrs. Protheroe & Morris (Three days).
TUESDAY,	FEB. 14—	Roses and other Plants, at the City Auction Rooms, by Messrs. Protheroe & Morris.
WEDNESDAY,	FEB. 15—	Roses, Fruit Trees, Shrubs, Border Plants, Bulbs, &c., at Stevens' Rooms. Japanese Lilies, at Protheroe & Morris' Rooms.
THURSDAY,	FEB. 16—	Orchids in Flower and Bud, 10,000 Liliun auratum, &c., at Stevens' Rooms.
FRIDAY,	FEB. 17—	Imported and Established Orchids, at Protheroe & Morris' Rooms.
SATURDAY,	FEB. 18—	Roses, Fruit Trees, Shrubs, Border Plants, Bulbs, &c., at Stevens' Rooms. Lilies, Roses, &c., at Protheroe & Morris' Rooms.

The Royal Horticultural Society. On Tuesday next the annual meeting of the Royal Horticultural Society will be held at South Kensington, and in view of all the circumstances, the event will be of unusual interest and importance.

In the first place it is now certain that the Society must remove almost immediately from South Kensington, where its career has been so thoroughly unfortunate. In the next place an opportunity is now offered for thoroughly reorganising the Society on a strictly horticultural basis, including most, if not all of the suggestions which have secured the assent, not only of the Council, but also of two general meetings. These suggestions are numerous enough and varied enough in all conscience, but there is, happily, substantial agreement on all matters of principle, while details must be settled in course of time as circumstances dictate.

As many of our readers already know, a strong outside committee has been appointed to confer with the Council as to the best means of reorganising the Society, and putting it upon a sound basis. That committee has had the advantage of the sugges-

tions of many of the most capable and trusted of horticultural representatives, through the medium of the Press and otherwise, and it is not the fault of the committee if more have not been in counsel together. So far the committee and the Council have acted loyally in concert one with the other, and there is every prospect that they will continue to do so. The committee has only been in existence a short time, but it has we believe already done good work; it has held several meetings, and, if we are well informed, it has already arrived at some important conclusions.

The first matter of pressing importance has necessarily been the question of site, and we are informed that there is now every probability of a site being obtained for the future operations of the Society so far as the metropolis is concerned. This will be eminently satisfactory to the Fellows, at least for the present. Excellent apartments is likely to be secured for the offices, and for the library and reading-room of the Society in Victoria Street, Westminster, while ample accommodation is available at a few minutes' distance for the exhibitions and larger meetings of the Society. So far as the Lindley Library is concerned it appears, according to the trust deed, that when the Society quits the South Kensington gardens the trustees have unrestrained liberty to place the library wherever they please, but remembering the history of the trust and all the circumstances of the case, there is little doubt that the library will in future, as in the past, be placed in the rooms of the Society. The new apartments of the Society will, in all probability, be so convenient that the general utility of the library will be very considerably enhanced, and the trustees will in future be enabled to carry out their original intentions, and render the library much more freely available than it ever has been, or could be, at South Kensington.

As to the general policy of the Society, that has already been fully discussed publicly and privately, and the general principles affirmed at two general meetings already. Suffice it to say that it is felt that no aspect or section of horticulture should be neglected, and no section receive undue importance. The Society, it is hoped, will no longer be a purely Metropolitan Society, but an endeavour will be made to extend its legitimate influence by the formation of branches and the appointment of representatives in every district of the country. The constituency, it is hoped, will be greatly enlarged by the adoption of low rates of subscription for those who are not disposed to pay the higher amounts. Privileges and suffrages, it is hoped, may be conceded according to circumstances, so that horticulturists, of whatever department or grade—scientific, practical, social or commercial, rich or poor—may feel that they have not only interests, but rights, in the Society. These, we believe, are the high aims which the Council and the committee set before themselves, and we have every hope that in time we may look for the realisation of some at least of these objects. Such a programme must evolve and be executed bit by bit, and necessitates patience and time for its fulfilment. Circumstances are sure to arise which will demand modification in this or in that respect, but success will be obtained exactly in proportion as the horticulturists of the Empire will consent to subordinate their specialist fancies, their sectarian prejudices, and their personal interests to the general welfare of the body corporate.

The existing charter is practically obsolete in many of its provisions, and must undoubtedly, sooner or later, be replaced by a document more in accordance with the requirements of the times;

but as a matter of practical expediency it is felt by those who have considered the subject that the consideration of this cardinal reform must for the present be postponed. In the meantime a great deal can be done in the direction of necessary reform by the recasting of the bye-laws, and this operation will, we believe, be taken in hand immediately after the annual meeting.

The main business of that meeting will consist in the election of new members of Council. The whole of the Council, it is announced, will resign, but it is proposed that, while some of the old body will remain, a relatively very large infusion of new members, selected by the committee, will take the places of others who propose to resign, and either not to offer themselves for re-election, or who if re-elected will decline to serve. The construction of the charter and bye-laws is such that, without some such procedure, the wishes of the Fellows and of the committee cannot be carried out. This is a fact that must be remembered, as the Council is sometimes exposed to blame for having done things which under existing regulations it could not legally avoid doing. It must suffice to say that, so far as we can judge, there is every disposition on the part of the Council, collectively and individually, to act for the best as regards the welfare of the Society quite irrespectively of any personal consideration. This has been shown already, and we believe that on Tuesday next other striking illustrations of this self-abnegation will be manifested. A very large proportion of the new Council will, it may confidently be expected, consist of gentlemen recommended by the outside committee, and who will in future be members of both bodies, and so keep in touch with outside feeling and with the wishes of the horticultural community at large.

Our recommendation to the Fellows on Tuesday next is so to bestow their votes as to support the general policy of the committee and of the Council, and not to complicate matters and perhaps destroy the budding prospects of the Society by the display of injudicious prejudices, and ill-timed personal motives, however justifiable they may seem to be.

NATIONAL AURICULA AND PRIMULA AND NATIONAL CARNATION AND PICOTEE SOCIETIES (Southern Sections).

—A meeting of the committee of the above Societies was held at the rooms of the Horticultural Club, on Tuesday, February 7, when it was decided to hold both exhibitions under the auspices of the Royal Horticultural Society—the Auricula and Primula exhibition on Tuesday, April 24; the Carnation and Picotee exhibition on Tuesday, July 24. The schedules were revised, and will be printed as soon as it has been determined where the exhibitions will be held.

ROYAL SOUTHAMPTON HORTICULTURAL SOCIETY.

—The annual general meeting of the members of this Society was held on Thursday, the 2nd inst., in the Philharmonic Rooms, and was attended by about seventy members, and W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, was elected President, in the place of Lord MONTAGUE, who retires. The other officials for the forthcoming season were likewise elected.

FLOWERS IN SEASON.

—We received recently from Mr. J. CHAMBERLAIN'S gardens, Highbury, Birmingham, a beautiful bunch of flowers of the twining Amaryllidaceous plant, *Bomarea patococensis* (conferta). The rich crimson funnel-shaped flowers are highly decorative in the winter show-house; but as yet the *Bomareas* are not common in gardens in spite of their almost unrivalled attractiveness. Mr. COOPER tells us that the plant from which the branch he sent was cut grew in a corridor, the temperature of which is that of a cool

LILIA ELEGANS VAR. NYLEPTHA.

Illustrated from a photograph by Mr. J. C. ...

greenhouse. With this came flowers of *Laelia anceps* Morada—one of the finest of the dark-lipped section. It was evident that the plant from which it was taken was well grown and long-established, the spike being very robust, and flowers of large size. Of a glorious *Anthurium* received from the same source we may speak later on.

LINNEAN SOCIETY OF LONDON.—The next meeting will be held on Thursday, February 16, at 8 P.M., when papers will be read:—1. "On Self-Fertilisation and Cleistogamy in Orchids," by H. N. RIDLEY, Esq.; 2. "Notes on the Birds and Mammals of Hudson Bay Territory," by Dr. JOHN RAE.

LETHORION.—A correspondent writes that, on trying this newly-introduced insecticide with a box of matches in his hand an explosion took place, which seriously injured his hand, the box of matches being quite burned up. He thinks that a caution ought to be given with such dangerous compounds. We deemed it right to communicate with the inventors of this substance, who reply that there are no explosive materials in the Lethorion, and that the "explosion" in question did not proceed from the Lethorion, but from the incautious way in which the matches were used. The inventors would do well to submit their invention to chemical analysis, in order that the public may be reassured on this head. There seems no doubt that the invention is a very useful one, but common sense demands that ordinary care should be taken in its use, and in this case, according to the complainant's own statement, this does not seem to have been done.

CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—On the 22nd inst. E. W. BADGER, Esq., Birmingham, will deliver an address "On the Advantage to Gardeners of a more thorough Knowledge of the Science as Contrasted with the Art of Gardening." At a later date he will discuss the raising of hardy fruits (Apples and Pears particularly) to bloom later than most of our existing kinds do, so as to escape or minimise the effects of our late spring frosts.

READING HORTICULTURAL SOCIETY.—The annual spring exhibition of this Society is fixed for June 6, a week or so later than usual. The summer exhibition will take place on August 15, both, as usual, in the Abbey Ruins.

READING CHRYSANTHEMUM EXHIBITION.—This, which is under distinct management from the Horticultural Society, will take place on Friday, November 9, in the spacious Town Hall. The Hon. Secretary is Mr. RICHARD CATCHPOOL.

UNITED HORTICULTURAL BENEFIT AND PROGRESS SOCIETY.—The annual meeting of the members of this Society will take place at the Caledonian Hotel, Adelphi, on Monday the 13th inst., chair to be taken at 8 P.M. During the past year a considerable number of new members have joined the Society; and there has also been a very satisfactory addition to the number of honorary members, the latter subscribing one guinea per annum.

NOTTINGHAMSHIRE HORTICULTURAL AND BOTANICAL SOCIETY.—The monthly meeting of the Society will be held at the Mechanics' Institute, Nottingham (Room No. 75), on Wednesday, February 8, at 7:30 P.M., when a paper on the Cineraria will be read by Mr. J. MEADOWS, Basford. Specimens of cut flowers, fruits, &c., will be exhibited.

CHINESE PRIMROSE MAGENTA QUEEN.—Mr. B. S. WILLIAMS is about to send out a new variety under this name, and has forwarded us some detached flowers of it, which are of medium size and good form. The petals are irregularly fringed, of a rich magenta-crimson, while the eye is five-sided, brownish, with a few yellow streaks, and the mouth and tube a clear golden-yellow.

HARPENDEN HORTICULTURAL SOCIETY.—The Secretary of the above, Mr. J. J. WILLIS, informs us that the tenth annual show of this Society has been fixed for Wednesday, August 29.

JARDIN DES PLANTES.—We have received a copy of the *Index Seminum*, or Catalogue of Seeds for exchange. Its richness may be estimated when we say that the list occupies seventeen quarto pages of four columns of close type. Communications should be addressed to Professor COANT, 27, Rue Cuvier, Paris.

A NEW PARK FOR BERLIN.—Recently a public park has been opened in the southern part of Berlin, which, in honour of Her Imperial Highness the Crown Princess, the patroness of horticulture, has been named the Victoria Park. The site, which lies on the northern slope of the Kreuzberg, is, in so far, very favourable for the landscape gardener, that fine views of Berlin can be obtained from the higher ground. The idea of forming a park here is an old one; but it is only recently that the difficulties that beset the carrying of it out have been overcome, and the plan carried out.

IRIS STYLOSA ALBA.—Mr. T. S. WARE has kindly forwarded to us a flower of this rare and pretty Iris, which he states has been grown in a cold frame at his Tottenham nurseries. The flower is practically white, but there is just a suspicion of lilac in the standards, which are of one tint throughout; the falls have a pale cream tinge, with a bright yellow spot in the centre; the base of each segment is dull yellow. This Iris will certainly be welcomed in all gardens when it is better known.

CHLOROPHYLL IN THE EPIDERMIS.—The existence of chlorophyll in the epidermis or skin of leaves is generally thought to be very unusual. Mr. SPENCER MOONE, however, by some recent researches published in the *Journal of Botany*, shows that it is much more frequent than is commonly supposed.

EDINBURGH CHAIR OF BOTANY.—Several gentlemen are reported as likely to become candidates for this appointment including Professor BAILEY-BALFOUR, of Oxford, Mr. GEDDES, Mr. G. MURRAY, Professor McNAB, of Dublin, and Professor TRAILL, of Aberdeen. In so large a University there is room for two Professors, at least—one to undertake histology and physiology, the other morphology and taxonomy, as in the German Universities.

MR. P. J. BERCKMANS.—The *Horticultural Art Journal* (Rochester, U.S.A.) gives a portrait of this gentleman, the successor to MARSHALL WILDEN in the presidency of the American Pomological Society. Mr. BERCKMANS is a Belgian by birth, but migrated to the United States in 1850, and ultimately established himself as a fruit cultivator in Augusta (Georgia).

CAMBRIDGE BOTANIC GARDENS.—We have received a copy of the exchange list of seed issued by the Curator of the Botanic Garden, Cambridge, Mr. R. J. LYSEN, and which is a carefully prepared document.

COOL SHOW-HOUSE FOR ALPINES, &c., AT KEW.—A want long felt by those interested in herbaceous and alpine plants has at length been supplied by a house answering to the above description recently erected in the herbaceous grounds adjoining No. 2 Museum, and now open to the public. Lovers of outdoor plants who may have tried perhaps in vain to get good clean flowers of Hellebores, &c., during the past season of fogs and smoke will at once see the advantages of such a house as the above. Its length is 30 feet by 10 feet wide, with a path and stages on each side, and above all it is a cool house in every sense of the word, no artificial heat whatever being used. In private gardens the want of a house of this description would hardly, if at all, be felt, as much the same advantage would be derived by the aid of a bell-glass or handlight, and which

could be lifted at will by the owner. In a public establishment, however, such as Kew, plants that want protection of any kind—and there are a great many, especially during winter and spring—are far more appreciated when grown or shown in a place easily accessible to the general public. Many of the very choicest of our alpine gems, deprived of the kindly shelter of the warm snow, such as they get in their native homes, either refuse to flower or their attempts to do so are frustrated by our treacherous frosts and biting east winds. Such plants that were previously grown in the cold pits attached to that department, and which were seen only by those specially interested, will now be placed where they can be admired by all visitors to the gardens. There are many plants also not quite hardy enough in the open air during severe winters that will do well in such a house as the above, which at the present time is gay with such flowers as *Helleborus niger* and its varieties, *Snowdrops*, *Iris reticulata*, *Primula floribunda*, *Helleborus orientalis*, &c.

FILMY FERNS.—The famous collection of Filmy Ferns formed by the late Mr. COOPER-FORSTER, has been presented by his son, Mr. STUART FORSTER, to the Royal Gardens, Kew. Mr. FORSTER'S success in the cultivation of Filmy Ferns was exceptional, even when compared with the best managed collections known; and when it is remembered that Mr. FORSTER grew the whole of his plants in several small houses on the top of his house in Grosvenor Street, his success seems all the more remarkable. Some of the specimens he grew are unique for size and health, and it is satisfactory to know that the collection generally has not suffered under the care of Mr. STUART FORSTER, who had them in a specially constructed house at Binfield, near Bracknell, in Berkshire. Mr. COOPER-FORSTER was a frequent visitor to Kew, where the Filmy Ferns were of special interest to him. Until just previous to his death he freely exchanged plants with Kew, and he was always ready with suggestions and advice when the welfare of any precious plant at Kew was concerned. The Kew collection of these plants has always been rich, and now, with the addition of the collection formed by Mr. FORSTER, it stands without a rival. This is the second valuable gift of Ferns made to Kew recently, the other being that of the Carboneel collection, already noted in our pages.

PHYLLOXERA.—M. MILLANDER, according to the *Revue Horticole*, has ascertained, after prolonged experiment, that hybrid Vines obtained by the cross-fertilisation of European varieties with American forms resist absolutely the attacks of Phylloxera and other vegetable parasites. We can but be sceptical as to the validity of the term "absolute," but in any case we congratulate our neighbours on their perseverance in applying the resources of horticulture to the overthrow of their enemies.

TRINITY COLLEGE, DUBLIN.—The following plants are now in flower in the College garden:—*Iris Histrio*, *I. reticulata*, *I. r. cyanea*, *I. stylosa*—these are and have been lovely; as also early species of *Crocus*, in a frame; *Narcissus minimus* is fully open on a sunny outside border, and is by far the earliest Daffodil of the year. *N. pallidus praecox*, *N. Ard Righ*, *N. variiformis*, &c., are now good in pots.

A CONTRAST.—Germany has, according to *Agricultural Science*, thirty-three horticultural schools, of which the principal are at Potsdam, established in 1824; Proskau, 1868; Geisenheim, in 1872; and the Flora at Cologne, in 1872. Besides these, there are, not mentioned by our contemporary, the Pomological Institutes and Forest Schools. In Belgium there are two well-equipped schools, that of Ghent and of Vilvorde, the model of which, it will be remembered, formed so remarkable an exhibit at the Health Exhibition. France has a school of horticulture at Versailles, with a President, and nine Professors and forty scholars, who have free instruction for three years. Denmark, as we know, educates her gardeners highly, as she has done her dairy-

farmers, with the result that much too large a proportion of the butter trade in this country is in the hands of the little Scandinavian kingdom, while Ireland and our own grazing counties are falling behind; and, to revert to horticulture proper, we have not even the ghost of a school of horticulture; and Chiswick—poor Chiswick—is the only public establishment where even the semblance of an experimental garden is maintained. "Oh! but," it is said, "the educated gardeners are not practical—there is no work in them." Perhaps not in particular individuals; but is it not true that the Germans are practical enough to be able to oust us in practical and commercial matters simply from their superior brain-power—no, we will not say power, for that would not be true—but from more careful brain-development, just as in military matters they overcame the French in 1870?

"L'ORTICULTURA."—Under this title has been issued at Turin the first number of a monthly horticultural journal devoted to economic and decorative gardening. The new-comer is a well printed octavo, with woodcut illustrations. One feature of the journal consists in the publication, on a separate sheet, of an illustrated dictionary of botany. The specific names are all printed with a capital initial letter, which is, of course, an error.

"KEW BULLETIN."—The February number contains a list of the seeds of herbaceous plants which can be sent in exchange from the Royal Gardens, Kew, or distributed in small quantities among its regular correspondents. The list is a very rich one.

CHRYSANTHEMUM GUNNERSBURY HERO.—This is a very useful late blooming variety of the Japanese section, of a rich golden-yellow colour, and is a free flowerer according to Mr. A. J. GILBERT, gr. to Miss H. MANSELL, Queen's Road, Guernsey, who says:—"The Guernsey Hero Chrysanthemum is a root-sport from the well-known variety Mrs. Charles Carey, but it is a much better bloomer, and has quite a good habit. I have cut as many as seventy-eight blooms from a plant in a 14-inch pot." We have seen specimens of the variety, sent from Guernsey; the flowers were of good bright colour, full, and of good size. Certainly it is a good late variety.

BOTANICAL SOCIETY OF ITALY.—A National Botanical Society has been established at Florence. Professor CARDEL has been elected President, General RICASOLI and Professor ARCANGELI Vice-Presidents. Florence is particularly well placed for such a society, and we are pleased to hear that the Italian botanists generally are supporters of the Society. It is worth notice that this new Society in large measure originated with the Tuscan Horticultural Society, which is co-operating fully with the new Society.

NATIONAL HORTICULTURAL SOCIETY OF FRANCE.—A landscape gardening committee has been added to the other committees of this flourishing Society.

FORCED FLOWERS IN BERLIN.—It is matter to rejoice over, writes a correspondent, how much the interest in Orchids has increased in Berlin; and whereas formerly but very rarely Orchid flowers were to be observed in the florists' shops, this winter Cattleya, Oncidium, Odontoglossum, and, this last week, Cypripedium flowers were to be found in them every day. As regards the other flowers, these consist mainly of Violets and Lilies of the Valley; Roses, Camellias, Tulips, Hyacinths and Cyclamen are of course to be found everywhere. The last-named, as one-year-old flowering plants, bearing fifty and more blooms, and produced in large numbers, and find ready customers. In the fabrication of bouquets the foliage of Mahonia aquifolia has become an indispensable material, and it is scarcely possible to obtain one that does not contain some of it.

PUBLICATIONS RECEIVED.—*Review of Forest Administration in British India for the year 1885—86.* By B. RINNESTROP. (Simla: Government Central Press.)—*Agricultural Produce Statistics of Great Britain for 1887.* (London: EYRE & SPOTTISWOODE.)—*Bulletin of the Botanical Department, Jamaica.* (Kingston, Jamaica: Government Printing Office, 79, Duke Street.)—*Bulletin of the Botanical Department, Trinidad.* (Port of Spain: Government Printing Office.)—*Note sur la Culture de la Vigne sous serre.* Par CH. JOLY. (Paris: G. ROUGIER ET CIE., 1, Rue Cassette.)

NOTICES OF BOOKS.

GARTENKUNST UND GARTENSONST UND JETZT.
By H. JÄGER. (Berlin: Paul Parey. 8vo.)

"Gardening and Gardens Past and Present," is a *résumé* of the subject by H. Jäger, Royal Gardens Inspector, Eisenach, a competent authority on all such matters as concern the gardener, landscape gardener, and garden architect. Much of the work consists of condensed accounts of such gardens of antiquity as are to be found in ancient authors. This part could very well have been still more condensed, the matter having no horticultural value. The numerous examples given of gardens of the Renaissance, and yet more modern periods, down to the present day, are of much interest, and will be found capable of furnishing ideas to those engaged in laying-out and beautifying existing gardens, especially where this is brought about by architectural adjuncts, the living materials used—incomparably poorer than that now employed—not having survived to our day. A good many instances are given of that misdirected labour of former days, Topiary work, as found in French, English, Austrian, and Italian gardens, some of which is actually in existence, notably at Hatfield Palace and Schonbrunn. Mention is made of the several artists, either followers of Le Notre or his pupils, who created wonderful combinations of architecture and gardening throughout the continent of Europe. These were Druze, Perault, Desgardes, Chapelle de Lisle, Charles Revel, &c.

A good portion of the work is taken up by descriptions of gardens as laid out in England, a style that has given its name all over the Continent to the free and unconstrained treatment of the ground and of the materials used in forming garden scenes. Excellent examples of gardens of repute in Germany are given, and which the reader is assisted in reconstructing in his mind's eye by means of many excellent plans and sketches.

The book is furnished with 245 engravings of a great variety of garden objects, garden scenery, and plans, architectural furnishing, &c., and is well printed on good paper.

LÆLIA ELEGANS VAR. NYLEPTHA.

(SEE SUPPLEMENTARY SHEET.)

PRESERVING the same habit of growth and form of flower as the type figured in *Select Orchidaceous Plants*, the beautiful variety which we illustrate from an excellent photograph by Mr. Herbert Measures from the specimen in his father's collection at The Woodlands, Streatham, differs materially in colour and in the fine development of its showy labellum, the front lobe of which measures nearly 2½ inches across. Each flower has a breadth of 7 inches; the sepals and petals on first opening are faintly tinged with rose, but change to sulphur-yellow as the flower ages; the tube of the labellum is pure white, the erect tips of the lateral lobes are crimson, and the front portion a rich crimson edged with a lighter colour. The stems of the plant are 2 feet 6 inches in height, and have much the appearance of a stout Cattleya guttata, which, with the invariable small spots in the segments of all the varieties of *L. Turneri*, and other contributory evidence, have given rise to the reasonable supposition that they may be derived from the natural intercrossing of varieties of *L. purpurata* and *Cattleya guttata*; and the consequent expediency for separating them from the other branches of the *L. elegans* group, which probably sprung from the union of *L. purpurata* and *Cattleya intermedia*, all the plants mentioned growing together.

The hybrid character of the whole group is sufficiently demonstrated by the various stages of imperfect development always exhibited in four of their pollinia. However, no matter what its origin, the

noble variety under notice, belonging to R. H. Measures, Esq., is very distinct and beautiful. J. O'B.

HYBRIDISATION.

LIKE Professor M. Foster, I read the inquiry of "A. B." (p. 121) as to whether hybrid plants have any special tendency to reproduce themselves by buds instead of by seeds, and I in part agree with the editorial appendix, in which you infer that such may really be the case. Professor Foster's instance of *Iris balkana* crossed with pollen of *Iris Cengialti* is very interesting, but, as I surmise, the fact of his having cut the flower was conducive to the bud or vegetative growth being produced by the hybrid plant, and not the fact of the hybridisation itself. Some *Iris*s usually adopt this vegetative method of reproduction. For example, I may quote the *Maricas*. *Marica gracilis* flowers here nearly every year in a warm stove. Its flowers are very lovely and very evanescent. It rarely seeds in cultivation, but here, with us young plants are constantly produced from the floral region of the flattened scape. At flowering time the scape is moderately rigid and erect, but the development of the vegetative buds into little plants has the effect of rendering the scape less rigid, and finally, the weight of the young plants, and its own elongation after flowering, cause it to topple or flop over, and the scape dangles over the side of the stage; the young plants also reverse their position by turning upwards to the light. In a state of Nature these scapes—which are 2 to 3 feet in length when fully grown—would fall on the ground at about that distance from the parent plant, the result being a "rotation of crops," i.e., new soil and locality for the young plants as borne at its apex. The non-production of flowers, as in the Potato Onion; or the artificial removal of flower-buds, as in the case of *Lilium*, of the *L. Wallichianum* or *L. longifolium* section, often results in the formation of buds in the leaf-axils, and always so if the stems be bent down and buried in the soil or earth. Some *Allium*s are often very chary in producing flowers. A. anomalum just occurs to me as an instance of this kind. Now and then it does produce flowers, but the plant seems quite to mistrust its sexual organs for the purpose of reproduction, and resorts to the device of producing bulbils or bulblets, as in its esculent ally the bulb-bearing Onion. The genus *Agave* may be divided into two sections—indeed it is so divided naturally; the flowers of *Agaves* proper being generally fertilised by flies and bees, and so seeding freely under cultivation; while *Fourcroya*, which in general appearance agrees with and resembles *Agaves* in all essential particulars, rarely or never sets a seed, although bulb-like buds are produced in quantity, and these, within certain limits, serve to reproduce the parent plant. A good example of increased vegetative development is constantly observed in *Feras* which rarely or never produce spores *Adiantum Farleyense* and *Polypodium vulgare* var. *cambricum* may be cited as good illustrations of what I mean, seeing that both exhibit a much larger leaf area than either of the sexually fertile parent types from which they have originated.

I more than doubt Professor Foster's idea that "hybrids have a greater tendency to transgress morphological laws than offspring born in more lawful wedlock." My own opinion is that cultivation (other than hybridisation) is far more conducive to the leaning towards teratology; and I am convinced that cultivation, including the act of cutting off the only developed flower on the hybrid *Iris balkana* × *Cengialti*, was the predisposing cause of the young plant's appearance on the flower stem. That sexual organs in plants are the outcome of diminished, restricted, converted, or altered vegetative energy seems to me a fact difficult to disprove. That there are these two conflicting powers at work in all vegetative organisms is as clear to most gardeners as is light from darkness. All the best efforts of gardening as a science depend on the due encourage-

ment and restriction of vegetative energy—or we may call it leafy growth. To what end is all our root-pruning, planting in restricted areas, or grafting strong growing plants as scions on restricting stocks if it be not to encourage the production of sexual results in the shape of flowers and fruits? I used the above illustration of "light from darkness" in a double sense, knowing that light alone restricts vegetative development (I do not say growth) just as darkness facilitates the unfolding of vegetable fabric or sun-woven tissues of all kinds.

Some few years ago General Pleasanton started experiments with coloured glasses applied to the roofs of plant-houses, and especially vineries; and he also started the idea that the violet rays of the spectrum rendered Grape Vines more productive. He was laughed at by practical men, and even by chemists and others, at the time, mainly because although his crop was a large one, the quality of the fruit was not so good as other cultivators could grow under ordinary white glass roofs. Now, I see by a newspaper paragraph that no less an authority on vegetable physiology than "the great Panjandrum himself"—the renowned Sachs—has discovered that violet rays do really conduce to the production of flowers as opposed to mere leaf-growth in plants generally; so that at least half a truth lay hidden in General Pleasanton's vinery after all.

I must apologise for taking up so much space in thus offering some few "guesses at truth," and I submit with all deference to my good friend, Professor Foster, that our editor has had far more reason to thank the ordinary cultivator than the manipulative hybridiser for examples of misbehaviour amongst garden plants. *F. W. Burbidge, F.L.S., M.R.I.A.* [What about *Cypripedium Sedeni* × ? Ed.]

CRESTED FERNS.

In some species of Ferns the crested or tasselled varieties are very elegant, while in other cases it is quite a question of taste as to whether the curious multifid growths add much to the normal beauty of the species. However, crested Ferns are very popular at the present time, and several additions have recently been made to the list, both from those species that have not hitherto departed from their natural character, and improved varieties of the older crested sorts.

It is remarkable that these crested forms rarely revert to their normal state when raised from spores. Some slight variations occur generally, and occasionally a very distinct form presents itself; but I have large quantities of seedlings growing together where the variations have been very slight indeed.

The varieties of *Pteris serrulata* and *P. cretica* are among the most popular of the crested Ferns; of *P. serrulata* there are many distinct forms. First-class Certificates have been awarded for several varieties at different times, the first being to Messrs. Veitch & Sons in 1863, the variety being named *P. serrulata cristata*; the next came from Messrs. Cripps & Co., in 1866, named *P. s. polydactyla*. This was followed by one from Mr. Edwards in 1869; and in 1872 three varieties obtained first-class honours—two from Mr. Chambers, of Isleworth, and one from Mr. Dixon. I must not omit the Chiswick variety, which obtained distinction in 1870, and is now considered the best crested form of *P. serrulata major*. Among other varieties that have gained distinction May's variety of *compacta* is a useful one, and Naylor's variety is a distinct intermediate form. The crested form of *P. cretica* is very pretty; there are also some crested varieties of *P. cretica albo-lineata*, *P. Mayi* being the best; this variety is becoming very popular; it is of dwarf compact habit, and very regularly crested. *Microlepia hirta cristata*, a very elegant Fern, the fronds terminating in a light tasselled crest, the side planes are also slightly crested at the extremities. The crested form of *Lomaria gibba* is another very pretty Fern when seen in good condition. The *Gymnogrammas* contribute some good crested forms, of which *G. Wettenthaliana* (silver) and *G. Parsonsi*

(golden) are the most distinct. Of *Adiantums*, the most useful crested form is *A. cuneatum grandiceps*; the fronds are more elongated than in the type, and terminate in a broad tasselled crest. A slight variation of this form was exhibited at Kensington last spring, and was awarded first honours under the name of "Gordon's tasselled" *A. Ludemannianum*, is a curious form in which the pinnules are produced in tufts on an irregularly divided rachis. *Lastrea Richardsi multifida* is very pretty when grown on freely from a young state without receiving a check. *Nephrodium molle corymbiferum* is an old favourite. There are two crested *Davallias*, *D. Mariesi cristata* and *D. elegans polydactyla*; both of these have gained First-class Certificates, but I cannot see much to admire in them, especially the first-mentioned, in which the crest certainly detracts from, rather than adds to the elegance of one of the most lovely Ferns grown. In *Nephrolepis davallioides furcans* we have one of the most elegant of all the crested Ferns. *N. Duffii*, is also a distinct and pretty variety. *Woodwardia radicans cristata*, *Doodia aspera multifida*, and *Osmunda japonica corymbifera*, are desirable varieties, especially the last-named, which is one of the most unique examples we have in all the Ferns which produce multifid growths. The crested forms of some of our native Ferns are very numerous, especially the *Athyriums* and *Scolopendriums*; of the former many of the varieties are very elegant. *Lastrea filix-mas* is also prolific in varieties; *Polystichum vulgare*, *Osmunda regalis*, and *Polypodium vulgare*, all produce crested varieties. *Pteris*.

SCOTLAND.

NORTH OF SCOTLAND HORTICULTURAL ASSOCIATION.

The last meeting of one of the most successful sessions of this Association was held in the Music Hall Buildings, Aberdeen, on Friday evening, the 3rd inst. There was a good attendance. The feature of the evening was the reading of a paper sent by Mr. J. Fraser, Kew Green, Surrey, entitled "The Influence of Light on Plants, as applied to Horticulture." The writer treated his subject in an instructive and exhaustive manner, and was warmly thanked for his communication. Discussion followed the reading of the paper. The usual vote of thanks terminated the meeting and the session of 1878-8.

DUMFRIES HORTICULTURAL IMPROVEMENT ASSOCIATION.

At the usual monthly meeting, held in Greyfriars' Hall on the 2nd inst., Mr. Kiddick in the chair, Mr. Rowe, Nunfield Gardens, Dumfries, read an interesting paper on "Orchid Culture." He said that one of the essential points in the culture of Orchids was suitable houses, the houses he preferred being light span-roofed structures with the ends facing north and south. He strongly recommended the advisability of storing all the rain-water possible in tanks constructed beneath the stages. Although much had been written about the practice of heating the water for Orchids, he had a small pipe in the tanks for that purpose in cases of emergency, such as having to water soon after heavy rains or snow-storms.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

The ordinary monthly meeting of this Association was held in 5, St. Andrew Square, Edinburgh on the 5th inst. Mr. D. P. Laird, President, in the chair. Mr. Robert Lindsay, Curator of the Royal Botanic Gardens, Edinburgh, read an interesting paper, entitled "Historical Plants."

An interesting exhibit of spring flowers from Mr. Smith, of Newry, was on the table; it contained some interesting Croci, *Sisyrinchium grandiflorum*, and a large form of Snowdrop, named *Galanthus nivalis maximus*, amongst others.

VEGETABLES.

RUNNER BEAN NE PLUS ULTRA.

In order to get this Bean up to the high character in which it was seen in the conservatory at South Kensington during the past summer, some twenty years' persistent work of selection had been gone through. It originated with Mr. Neal, gardener to P. Southey, Esq., Bampton, Oxford, and he began first by selecting pods with five beans, and went on until he had got six, and eventually seven and eight beans in a pod. During these twenty years Mr. Neal did not buy a single bean, but worked away in the most persistent manner with his own selections, until he has evolved what may be termed a perfect Runner Bean, for the pods are long, straight, and symmetrical from end to end. Mr. Neal has calculated, that for every bean he has added to the pods he also secured an additional inch of solid flesh that can be eaten. Mr. Neal has now succeeded in obtaining pods from 10 to 14 inches in length, as straight as it is possible for them to be grown; and he asserts that, if thirty beans of his *Ne Plus Ultra* be planted $1\frac{1}{2}$ foot from bean to bean they will produce more than a pint of ordinary Scarlet Runners. If any one would have fine Runner Beans for show purposes, let him dig out a trench and manure it well as he would for Celery, and by keeping the plants well watered they will grow to a length of 14 feet. One successful exhibitor grows his Beans in circles, and trains them to tall stakes. *R. D.*

THE FLOWER GARDEN.

HARDY WALL PLANTS.—The majority of these may now be pruned, nailed, or tied in, and in doing so keep a watchful eye for such insects as scale, and take means to eradicate them. In extreme cases of insect attack we would advise that the plants be cut down to within a foot of the ground, and the branches burnt forthwith. Far better to sacrifice one season's crop of bloom than to have disfigured plants. *Ceanothus Veitchii*, *Jasminum officinale*, and the different varieties of *Loniceras* should have last year's growths cut back to a short spur. In *Keria japonica* cut out all weak and spindly growths, reserving only the strongest, from which the unripened point only need be removed. Late flowering Clematis of the Jackmanni type should be cut in rather close, whilst those belonging to the early flowering sections and which produce flowers on shoots of the previous year's growth should be merely thinned out, retaining the strongest and best ripened shoots. Tea-scented Roses on south and west walls which are required to produce early flowers may be pruned; and the following, immediately after flowering:—*Chimonanthus fragrans*, *Forsythia viridissima*, *Garrya elliptica*, and *Jasminum nudiflorum*.

Propagating.—Where the means for early propagation exist, and when strong, healthy cuttings are obtainable, *Verbenas*, *Lobelias*, *Alterantheras*, and *Iresines*, may now be put in. An easy and quick method of propagating these is to employ shallow boxes 4 inches deep, filled to within an inch of the top with suitable compost, over which put a layer of sand; cover the boxes with panes of glass, and place on the hot-water pipes in a house where a temperature of from 65° to 70° is maintained; so treated, they will root in less than a fortnight. *Tropaeolums*, *Gnaphaliums*, *Heliotropes*, and other soft-wooded bedding-out plants, may be now propagated. *Dahlias* and tuberous-rooted *Begonias*, where it is desired to increase the stock—the former by cuttings and the latter by division when the young growth is about an inch high—may now be started in heat in boxes. A fortnight hence will be early enough for increasing the general collection of bedding plants.

Hotbeds.—When circumstances compel recourse to these means of propagating the treatment of the fermenting material may at once be taken in hand so as to have a bed in readiness by the end of the month. Although these beds are but poor apologies for a propagating pit hotbeds will serve their purpose very well if not made use of at too early a period, and if great care be exercised in giving air and

otherwise guarding against injury to the inmates by ammoniacal gases.

Flower-beds.—The severe frosts having caused upheaval of spring-flowering bedding plants, these should be pressed down with the hands, taking the opportunity to hand-weed the beds where found necessary. Autumn-planted Carnations and Pinks, and newly-planted herbaceous stuff should also receive this kind of attention. *J. Horsefield, Heytesbury.*

THE LAST OF ITS RACE.

"Nor a thing to be regretted" was the reply of a Philistine to whom the photograph was shown, and, indeed, the tree of which we give an illustration (figs. 30 and 31) cannot be commended for its symmetry; but beauty is often one of the most really unimportant of attractions, and so it is in this case. We do not suppose the last of the aborigines of Tasmania, who died not so very long since, was a very attractive person, nor, in all probability, did the last old lady who spoke the Cornish tongue find many admirers for her beauty sake. The interest attaching to the tree represented at p. 181 is, that it is the last existing representative of its race in the island of St. Helena. Formerly, doubtless, there were many more, but goats and the destructiveness of man have destroyed this and many other species peculiar to that remote islet. As in point of structure it possesses peculiarities of its own, it is evident that the loss of such a tree is equivalent to the tearing out of a page of a record, or, to suit the Philistine mind, let us say the destruction of a page of a ledger. In this country, indeed, generally, Composites are herbs, or at most bushes. Asters, Senecios, Daisies, Chrysanthemums, Dahlias, as all know them in our gardens, are not to be classed with trees, but here we have a plant nearly allied, generally, to Aster, which forms a good sized tree with spreading naked branches, bearing small stalked, spatulate, toothed leaves crowded towards the ends of the branches, and which leave when they fall very prominent cicatrices. The heads of flowers are borne in dense clusters, as shown in the smaller illustration (fig. 30). The tree in question is about 20 feet high, and grows near the entrance gates of Longwood, the place of the enforced retirement of Napoleon, who must often have seen it. Originally described under the name *Psadia rotundifolia* by Sir Joseph Hooker, it was figured by Melliss in his work on St. Helena, p. 294, t. 41, and is mentioned by Hemsley in the "Report of the Botany of the Challenger Expedition." So that the record of the tree is not likely to be lost, while specimens exist in the Kew herbarium from Burchell (anno 1806—1808), Melliss, 1868 and 1877, as well as from Mr. D. Morris, the Assistant-Director of the Royal Gardens, Kew, who gathered specimens in September, 1883, and succeeded in introducing seed to Kew, where it has germinated. We are indebted to Sir Joseph Hooker for the use of the photograph.

HOME CORRESPONDENCE.

GARDENERS' ORPHAN FUND.—For the information of your correspondents who evince so warm an interest in this Fund, and to whom I feel deeply grateful, I shall feel obliged if you will kindly allow me to state that the question of money-boxes was considered at the last meeting of the Executive Committee, with the result that sample boxes are to be presented at the next meeting for approval; a number of boxes of the approved pattern will then be ordered for distribution among such of our friends as will kindly undertake the charge of them. *George Deal, Chairman.*

WHAT IS A "NELIS" PEAR?—It is often wondered what is the meaning and origin of Nelis applied to a Pear. Perhaps it is easily explained, and perhaps the following suggestion is libellous. A gardener who raised a new late Pear, asked a literary friend for a good name for it. He suggested "autumnalis" which the raiser adopted, but wrote as two words, "Autumn Nelis." Soon after a rival raiser brought out a still later Pear, which was to supersede it, and was accordingly named the "Winter Nelis" (or *winternalis*). *C. W. D.* [And this is how history is written! Now for the facts. John Charles Nelis was a well known Belgian pomologist, who died in 1834,

as may be seen from Leroy's *Dictionary of Pomology*, where our Winter Nelis is described and figured as *Bonae de Malines*. Ed.]

MEDLAR JELLY.—I enclose a receipt for making Medlar jelly, which has been in the family for years, and is made every season with great success. If properly done it should be a stiff jelly, and improve if kept some time before use. Medlars are very commonly grown in Jersey, and the finer the fruit the better the flavour:—Take some Medlars when quite ripe, wash and put them into a preserving-pan, or boiler with close-fitting lid, with just as much water as will cover them. Let them simmer slowly till they become a pulp (which will be from four to five hours), then strain through a jelly-bag, taking care not to squeeze with the hands at all, as that would make the jelly muddy, but let it drain to the very last drop, as the last of the liquor is the richest. To every pint of juice add three-quarters of a pound of loaf-sugar, and boil for about one hour. When cold it will be a stiff jelly. *M. Gibaut.*

ARALIA JAPONICA.—Did the dry summer of 1887 affect this species so as to prevent it blooming in the autumn? I have a fine specimen in the open air on a south aspect that has grown freely and

FIG. 30.—*PSADIA ROTUNDFOLIA.*

flowered profusely for a few years past, but for some reason not a single bloom was put forth this season. The buds plumped up as usual during the end of the summer, but not one put forth an inflorescence. On examining the buds to-day I find every one of them completely rotten, though not a leaf of the large plant bears a trace of injury from the sharp frosts. Strange to state, not one of my plants in a cold-house bloomed also, though in former years they scarcely once failed to do so. Is this a general experience? *R. D.*

HARDINESS OF LAPAGERIAS.—Referring to Mr. J. Roberts' note on this subject (p. 152), I may remark that I have often wondered how the large number of plants placed in the open air about the grounds of Colston Bassett, Biaghams, Notts, by the late Mr. G. T. Davey, have fared. They were, I believe, planted two or three years previous to the visit of the Royal Horticultural Society to Nottingham, and Mr. Davey's idea was to imitate as far as possible the appearance of the plant in its native habitat, and to this end the plants were placed in the ground just within the fringe of shrubby borders, clumps of shrubs, &c., so that the shoots could attach themselves to the branches, and, growing upwards, find their way among the outer branches and there bloom. I think I am right in stating that more than one hundred plants were placed out at Colston Bassett, and it would be interesting to know if any of them have survived. Colston Bassett lies between Nottingham and Grantham, and it would, I assume, be a colder locality than round London. Mr. Roberts' experience with seed of the white *Lapageria* is, I think, the general one. I have never heard

of a white variety being produced from seed taken from a white parent, but it may have happened. Seed of *Lapageria rosea* is frequently offered in seed catalogues, but the white seldom, if ever. It is the fact, that the white *Lapageria* has to be obtained by means of layers that makes it comparatively scarce and high in price. The layering of *Lapageria alba* is done on a somewhat extensive scale at the Royal Exotic Nursery, Chelsea. The shoots are laid down on a bed of sandy peat about the months of November and December, and slightly covered; in February and March they break into upward growth at various points, and root downward also, and the ascending shoots twine themselves about twine suspended from the roof. When strong enough, the rooted plants are removed, potted, and grown on into size for sale. *R. D.*

THE ST. BRIGID HELLEBORES.—I now send you a few seedling Christmas Roses raised in the garden of Mrs. Lawrenson, near Dublin, by that lady. They are all the produce of the seeds of *H. niger angustifolius* cross-fertilised with pollen of *H. n. altifolius*, *H. n. ruber*, *H. n. caucasicus*, &c. The seed was gathered and sown in 1885, so that the fifty-one plants (seedlings) now in flower are only about two years old from germination (Jan., 1886). All throw the flowers well up on the stalks. Nearly all have pale or apple-green leaf-stalks, and flower stems more or less dotted with red. Some have rosy buds and the sepals behind heavily flushed with rosy-pink, others are pure white. The leaves resemble, 1, *H. niger* type; 2, *H. n. angustifolius*; 3, *H. n. altifolius*; and the flowers fall into three groups—1, deep or cupped flowers, having broadly imbricated sepals; 2, flat or saucer-shaped flowers, with broad and imbricated sepals; and 3, starchy flowers—the sepals not or only very slightly imbricate. Some have flesh-pink or even blood-coloured stigmas, others whitish or greenish ones. I and Mr. F. W. Moore have numbered the fifty-one plants, and made a classified report of them. So far as we know this is the first and only batch of Christmas Roses ever raised of which the history is clear and authentic. At the time of fertilisation no other Christmas Rose—*i.e.* forms of *H. niger*—were in the garden except *H. niger angustifolius* (St. Brigid)—and in order to fertilise the stigmas of the St. Brigid variety flowers were obtained from Mr. Walter Ware of Bath. The St. Brigid variety never seeds by self or insect fertilisation in Mrs. Lawrenson's garden, so that there can be but little doubt of these being true cross-bred varieties, especially as the size, aspect, and coloration of plants, leafage and flowers show them to be intermediate in character between the parent forms. They, however, possess that increase of size and added vigour so generally characteristic of cross-bred seedlings. I am anxious that your readers should know of the ease and rapidity with which beautiful forms of Christmas Roses may be raised from seed if judicious cross-fertilisation be resorted to and the ripened seeds at once sown. *F. W. Burbidge.* [A beautiful and interesting selection. Ed.]

CYCLAMEN COUM.—The treatment suggested by your correspondent, Mr. G. F. Wilson, in your last issue, is, I understand, exactly the treatment given by Mr. Atkins, of Painswick, who succeeded in raising quite a new race, now bearing the name of Atkins varieties. Mr. Atkins styled the *Cyclamens* "a beautiful genus of limestone-loving plants, seeming to prefer a south or westerly aspect." In our own experience we have followed Mr. Atkins closely in the treatment, and our success is all that can be desired; indeed, taking the whole of the hardy *Cyclamens*, not even *C. europeum* excepted, I know of none that will not thrive all the better for a liberal admixture of lime rubbish, &c., in the soil. They delight in a free soil where stagnation of moisture is impossible. In chalk districts, such as that presented at Broxbourne, *Cyclamens* grow like weeds, and one may count seedlings of all kinds coming up by the thousand. *C. Coum*, as your correspondent says, with the above treatment, is a truly charming alpine, and no rockery, in my opinion, is perfect without them. *C. Atkinsii* and its varieties are the result of a cross between *C. Coum* and *C. ibericum*. These two species, if simply planted together, and left to themselves, will give the same results, although when grown apart the seed from either comes perfectly true to name. *C. neapolitanum* is another old species that one does not so often see in gardens as could be wished. It blooms in autumn, but just now the leaves on well-grown plants are a perfect picture, almost as interesting, indeed, and certainly more beautiful than many flowers. *D.*

SOLANUM CORNIGERUM.—In Mr. Ridley's notes on *Solanum cornigerum* (p. 756, Dec. 17, 1887), it is stated that "its native country does not appear to be known!" As a contribution to information upon the subject I may mention that *Solanum mammosum* is well known as a native of the West Indian Islands. In Jamaica it covers acres of pasture land, and becomes quite a nuisance to the "pen-keeper" (local for grazier). It is known to the negroes as "cockroach poison," from its being credited with the power of removing these pests to household comfort in the tropics. Without close examination, it appears to me that *Solanum cornigerum* should only be regarded as an abnormal form of *S. mammosum*, an opinion I shall take steps either to confirm or abandon at an early date. In Trinidad, *S. cornigerum* exists in quantity on waste lands near the sea. I have not had time as yet to note, but I expect to find the forms of fruit

charter, which appears essential for the working of the Society, to appoint a Board of Examiners to examine gardeners who are candidates for Associate membership. The Councils of the Institute of Chemistry and Society of Actuaries obtained similar powers a few years ago. At first they permitted all persons who were in practise to become members, but after a certain date no one was permitted to be elected Associate or Member without examination. Of course a certain number of "duffers" may at first get elected, but that cannot be helped. *A Member of the Fellows' Committee.*

BORDER CARNATIONS.—Last summer was the most prolific in seed production of border Carnations I have ever known. There is nothing like a hot dry summer for the setting of the flowers, the fertilisation being apparently accomplished naturally, that is,

Carnations at their best. Plants which bloomed this year similarly raised threw up a dozen stems each, and carried several dozens of flowers. Young plants in the form of fresh layers produce perhaps one stem only with just half a dozen of flowers, and of course should be the finest; but no appreciable effect is obtained in that way, unless some half-dozen of plants are clumped together. Strong seedlings not only send up their stems closer together, but as a rule they are shorter and stouter than are those from layers. Of course the best kinds should be so propagated as to ensure perpetuity, but when a plant, as was the case with mine here this season, gave some eight to ten layers, and as many hundred of seeds, from which will probably spring quality as fine as the best parents, it is not to be wondered at if the seedling method should find most favour in the production of Carnations. I wish to make it clear that flowers of the finest quality produced seed most liberally. It was not a case of perpetuating the worst, but really of the best, and that fact may well encourage many to go in for the growth of Carnations from seed. No seed—not even Sweet William—germinates more freely. No plants seem hardier, or in a comparatively youthful state more indifferent to heat or to cold, to wet or to drought. They do not like soot or smoke, but happily we are here still somewhat out of the reach of these atmospheric abominations. I grow a few selected French Carnations also, because they give, if smaller, at least very perfect double flowers, and some pleasing colours for buttonhole bouquets. I think them particularly pleasing, but probable as much can be said for all Carnations having the biggest form. *A. B.*

PEAS THAT POSSESS COLOURED FLOWERS.—In answer to an enquiry made by a correspondent ("Alpha") I give the names of some garden and field Peas which have flowers that are other than white in colour:

Imperial Dwarf Blue Pea—the flowers open green, like most other Peas, and remain veined and tinged with green.

Mummy Pea, of which Crown Cluster is one form, has two-coloured flowers.

Purple-podded Pea has flowers of bluish-violet, not so deeply coloured on the standards as on the wings.

Giant Sugar Pea (without parchment) has flowers of a purplish tint.

Pois Café, a Canadian variety of an agricultural class, has red flowers, and brown seeds; in *P. Géant*, the flowers are violet coloured.

Pois sans parchemin, Mange out demi-nain a Ciel noir: flowers violet colored.

P. s. p. à Cosse Jaune has flowers white and yellow.

P. s. p. à fleur rouge, has pale red flowers.

A Pea of the same name has violet flowers with a red keel.

Pois s. p. nain gris has flowers violet-coloured.

The German varieties of Sugar Pea (*Kapuziner Erbsen*) have generally red flowers.

Field Peas—Spring Gray Pea, Partridge Pea, Winter Gray Pea—have violet-coloured flowers. *Sans Parchemin.*

—In reply to your correspondent's enquiry, the three following varieties of the garden Pea have coloured flowers, viz., the old Crown, or bunch-flowering Pea (sometimes known as the Mummy Pea), the Purple-podded Pea, the tall Sugar or edible-podded Pea, and several varieties of the type. I have also obtained many other varieties with coloured flowers by intercrossing the white-flowered Peas with the above and the maple and grey Peas (also having coloured flowers, but usually considered as agricultural varieties), but the seedlings have little value for garden purposes. I do not know that I am right, however, in classing the Crown, Purple-podded, and Sugar Peas as varieties of the garden Pea in the sense sought by "Alpha," although all the sorts I have named intercross freely, and I should like to know if there be any recent botanical authority on the classification of Peas. I am not aware that any of the coloured-flowered Peas vary materially, excepting in the temporary variations which usually follow from intercrossing. The best descriptions of the various sorts of garden Peas are to be found in Messrs. Vilmorin-Andrieux & Co.'s valuable work, *Les Plantes Potagères*, of which there is now an English edition. *T. Loxton, Bedford.*

CHRYSANTHEMUM JUDGES.—Now that Chrysanthemum societies are engaged in the formation of the prize schedules for the coming season, the question of the judges should be well considered;

FIG. 31.—*PSIADIA ROTUNDIFOLIA*, THE LAST OF THE RACE. (SEE P. 180.)

credited to *S. mammosum* and those to *S. cornigerum* both on the one plant. *J. H. Hart, F.L.S., Superintendent Botanical Department, Trinidad.*

THE ROYAL HORTICULTURAL SOCIETY.—I think we shall all agree with Mr. Woodbridge's suggestion, that the Royal Horticultural Society should take powers in the new bye-laws to elect gardeners as Associate Members. I am sure that this suggestion will meet with every consideration from the committee of Fellows which has been appointed to confer with the Council on the best method of making the Society popular. It appears to me that it would be desirable to limit the period during which gardeners might avail themselves of the privilege of being elected Associates, say till May, 1889. I think that the Associates should pay a subscription of 10s. *G.L.*, and that they should not be qualified to be elected unless they had been, say ten years in the profession. I hope that the Council will take powers in the new

through atmospheric instrumentality. I am not referring to the small flowered Continental strain, which seeds fairly well generally, but to fine border flower of some ten or more colours, self predominating. Judging by the products of my own sowing of a moderate quantity of seed, which brought me late in the autumn (under glass) some 5000 plants, I must have saved enough seed to raise 50,000, and with such a lot thrown into our gardens it cannot be said that the Carnation is being neglected. No doubt the finest strain in the world throws some twenty parent single flowers, but that is the limit; therefore the reduction in the bulk will be slight. I was during December engaged in potting, dibbling out into frames, and otherwise disposing of my big lot of seedlings, and in a couple of months they will go out into the open ground, being planted up in beds in rows a foot apart for the first year. No doubt many will bloom during the autumn, and certainly the following year all will carry big heads of bloom. That is the way to see border

much of the popularity (with the exhibitors especially) of any society depends upon the awards. I consider that in a great measure many of our leading exhibitions owe some of their reputation to the absence of mistakes of this class, as well as to the value of the prizes; no matter what may be the value of such prizes, if any doubt arises in the mind of an exhibitor as to the judges appointed not being of admitted ability that exhibitor is very chary about sending to the show. A short time since one of your correspondents hoped to see only practical growers of the flower appointed, and not theorists. I am not so sure that the growers of Chrysanthemums are the only persons qualified to make the best judges. I think a man who has not been a grower for exhibition is quite as capable of judging the qualities of individual blooms as the grower himself, and in some instances makes a much better judge than a grower would who has had no experience as an adjudicator. I am quite prepared to admit that if a judge of acknowledged ability has the advantage of being a grower of the first rank, he has an advantage over the judge who has not the grower's practical knowledge, for the simple reason that he is able to give additional weight to those varieties which are admitted to require more skill in producing in the best condition, hence the advantage of possessing a grower's knowledge as well as a judge's capabilities. This line of argument may appear strange to some persons, I will, therefore, endeavour to explain my views, which are not hasty conclusions. Let us take two men, Mr. J. Wright and Mr. George Gordon, whom I consider to be two of our best Chrysanthemum judges, and men who are not perhaps regarded as growers, although they may have been so once, but I am not able to say. There are many other good judges of Chrysanthemums who I do not intend to slight in any way by omission, notably Mr. James Douglas, but as I understand he was formerly an exhibitor he does not illustrate my argument so well as the two former, because he is still a grower of Chrysanthemums, if not an exhibitor. Where are there two men who judge at so many Chrysanthemum shows as the two first-named? How such men gain such a wide experience is in this way. At one exhibition to-day they have before them a stand of blooms; in this stand is a specimen of Madame C. Audiguier, for instance, as a Japanese, and Lord Alcester among the incurved, which are regarded as being fine specimens. To-morrow they go to another place in perhaps opposite parts of the country: the same two varieties are placed before them, this time in a better condition than they were yesterday. Perhaps the day following, at another place, the same sorts are presented in a much worse condition than at either place; thus the key-bloom of each variety is gained—thus at all subsequent exhibitions where they may act, they know what form each variety ought to be presented in, thus each bloom gets its proper weight by comparison from day to day, as it is well known to them that such and such a sort was staged at one place in capital condition, and it ought to be so again, because what one grower can do with a certain variety another can do also. With the method of judging by points, as is now generally practised where the competition is at all close, each flower gets its just reward according to the condition it is presented in, and it is almost (if not quite) impossible to justify the awards in a large class of, say, forty-eight blooms, where competing stands are close. By any other method than point judging comparison of the stands is not so accurate, nor is it so quickly done. I have endeavoured to explain my views of the subject to the satisfaction, I hope, of those who do not agree with the appointment of men as judges who have not distinguished themselves as exhibitors. *E. Molyneux.*

FREESIAS.—I am glad to see the culture of these lovely plants brought to the front, as they form a valuable addition to our stock of choice winter flowers. Here Freesias have been grown more or less for five or six years with varied results; but this season they are very fine, some of the spikes being nearly 2 feet high, and with three or four branches, and this season I have quite changed the method of culture, with the results above stated. The bulbs are kept very moist, and in a temperature from 50° by night, and 60° to 70° by day, the place chosen for them being a shelf close to the glass. I believe it reduces the strength of the bulbs to dry them off. I had a strange experience with part of my stock during one season. The earlier plants were watered as long as the foliage remained green, were kept in the same pots on a dry shelf, and left there

till wanted for potting in August. They were then shaken out, repotted, and treated as in the previous season, but not a bulb of this batch could be induced to start; they remained in this state till the following, that is, last August, when they were again shaken out with the others that had bloomed, and were repotted, as this winter we wanted more white flowers. The whole stock were started at one time, all pushed at one time, and bloomed altogether, and no difference could be detected in any of them, all being good. Our stock commenced blooming at Christmas, and will last two or three weeks longer. Now for the lesson taught by the partial failure. I take it that the bulbs were kept too hot and dry for too long a period, and became too much dried. After the repotting we were sparing with water, as is usual with other newly potted bulbs. I may inquire here, Why water bulbs sparingly when in pots? If you plant a bulb in the open border it has to take its chance as to rain or snow, and most bulbs come stronger than those in pots. We have never watered our Freesias so liberally before from the potting time onward as was done this season, they having had more than double the quantity of water, and they are now twice as strong as formerly. I intend keeping them watered the whole of the season, and let them make their own push. When our plants began showing the spikes for bloom I said to my foreman, "Give them some farmyard manure-water;" and before they had been on high living for a fortnight there was a marked difference in their appearance. When in a large London nursery recently, and talking to one of the principals about these he said, "Why rest them by drying?"—remarking that they were grown to very large size in a private garden (he naming the place), and the gardener in charge of this garden never allowed them to dry off. *Pro.*

LYCORIS RADIATA AND AUREA.—Has any reader of the *Gardeners' Chronicle* ever grown and flowered these two Japanese bulbous plants? They are usually known in gardens as *Nerine japonica* and *N. aurea*, under which names they are often offered in bulb catalogues. If any successful cultivator (I know several who are unsuccessful) of these plants would kindly make known the details of the treatment he gives them, others besides myself would feel grateful to him. The genus *Calostemma*, of which there are three species known, two of them being grown in English gardens, are equally unsatisfactory under cultivation with *Lycoris*. Perhaps some bulbophile can show us how easy they are to flower "when one knows how." *W.*

IS IT POSSIBLE TO BE WHOLLY FREE FROM POTATO DISEASE?—I have grown a large number of different varieties of Potatoes, mostly new, from different firms, including Messrs. Carter, Sutton, Laxton, Tait, &c., kindly placed at my disposal for trial. The almost unprecedented drought in the three southern counties of Ireland prevented, in a degree, satisfactory comparisons as to quantity, quality, &c., but one result was general—there was not a single tuber of any variety in field or garden diseased or blighted, and up to this moment, either with myself, or in the three southern provinces, have I seen one. This fact, which I admit may differ from the experience of others, induced me to ask myself, as I now do you, the above query, or, in other words, the Peronospora fungus, not having appeared this year (season) past may we expect to be finally rid of it? [No.] You will readily see what an important matter this is. *W. J. Murphy, Clonmel.*

CYCLAMEN GROWING.—It has doubtless occurred to many, as it has to the writer of these notes, that this beautiful decorative subject, one of comparatively easy management, of varied hues of colour in its flowers—bright, pleasing, and charmingly diversified—with pretty foliage to boot—a plant that will give us flower, and that in a bountiful way, for six months of the year, and this just now when there is a decided dearth of other flowering subjects in fair Flora's domain—is not by any means cultivated to the extent or in the manner that it deserves. The "market growers" of it can be counted on the fingers of one hand: these may be trusted that the plant does not suffer under their management; but of the private growers—gentlemen's gardeners and amateurs—what shall be said of these? Ah! we have a sorry revelation to make in this connection, but "truth must be told." With only a few exceptions they are not at all happy in their management of this useful decorative subject. They mismanage, starve, neglect it; failure is

"writ large" on their undertaking in this matter, and hence the miserable displays, if displays they may be called—lingering death, rather!—that we occasionally lighted upon in our journeyings to and fro. This question of Cyclamen culture is beginning to be of much interest to the owners of gardens. They see brilliant displays of the plant at various trade establishments, and where the plant is well done, they purchase the seed, and yet success does not crown their efforts; not because the seed is not good, but because the methods of raising and growing the plant are not well understood. We heard recently of a gentleman who, after having seen one of these fine displays, wanted to engage a gardener who, amongst other things, could grow Cyclamens well. The gardener must then look to his own interests, and study the wants of these plants, as he does of other subjects with which he succeeds—a task which is not at all formidable—if he is to keep abreast of the times, thus enabling him to take up successfully the culture of a class of plants that has rapidly, by reason of its prettiness and adaptability, become a favourite with the public. The present time, when the Cyclamen, under proper management, is beginning to appear in its bright array, seems to be an appropriate one in which to draw the attention of the craft to this matter. *B.*

CYLINDERS FOR PHALÆNOPSIS.—The cultivation of these plants has recently been the subject of frequent comment and suggestion, the latest being that the use of salt was in some way beneficial to them. It has not been suggested how the salt affected the Phalænopsis, and the only good that I could see in its use would be in the destruction of vermin, such as slugs, &c. Certainly the salt would remain where it was put, and would not have the slightest effect on the atmosphere, as, for instance, ammonia would. In the use of cylinders, however, there is nothing hypothetical, nor even new; but they have proved so satisfactory since we have used them for Phalænopsis, that I hasten to recommend them to others who have not yet tried them. We use tall cylinders made of Teak, the shortest being 1 foot high by 4 inches in diameter; the upper half is filled with large pieces of charcoal and crock, and the plant has a little sphagnum about its base. The roots soon become attached to the cylinder, and the plants have grown wonderfully in the year or so during which they have been thus treated. When suspended in baskets the leaves of these plants are apt to get injured by coming into contact with the wire suspenders. (Has this strange occurrence ever been explained?) We have tried *P. grandiflora*, *P. Stuartiana*, *P. amabilis*, and *P. violacea* in the cylinders, starting only with a few to test the treatment, and the result is so satisfactory that this spring we intend planting all our Phalænopsis except *P. Parishii* in cylinders. We have lost a good many of the flowers of these plants owing to fog, and, curiously enough, whilst some plants have suffered severely, losing almost every bud, others have not suffered at all, although hanging by the side of the former. What is it in the fog that is so injurious to flowers—want of light, excess of moisture, or some deleterious gases held in suspension in the fog? How is it, too, that white flowers out-of-doors, such as Christmas Roses, and therefore exposed to the full influence of fogs, are not affected by them? Perhaps the Scientific Committee of the Royal Horticultural Society would think the subject worthy of investigation. *W.*

THE PAST FRUIT SEASON.—I think the experiences of the past year have been in many respects very useful ones, and will have been the means of inculcating some useful lessons in fruit growing. Those who always give the fruits of the garden a full share of their careful culture will have been well rewarded, although the past season was a most trying one. On gravelly soils generally fruit trees do not succeed for many years together, and fruit crops of good quality are not the rule, and especially would this be true under the heat and drought of the summer of 1887. By heavily mulching the soil in which the trees were growing, and by having planted their roots in loamy soil, and not in the staple soil of the garden, we are enabled here to get good crops of all kinds of fruit. How often do we find the bush fruits planted on a piece of ground and left unmoved for a great number of years, and as the bushes die off, as they inevitably will, are replaced by younger ones, but still in the old soil? This is a practice which most good cultivators will condemn—if only a few rows of each kind of young bushes, and which can be easily avoided in gardens by planting annually in fresh ground a few rows of

young bushes. In my opinion a succession of young trees and bushes should be kept up in all gardens of whatever size, and to do this a few of each would require to be purchased annually. This may cost a little money, but it is cheap in the end. Where deep cultivation of the soil on which the Strawberry is grown is carried out the ordeal of the past season will scarcely have been felt, the plants having borne magnificent crops of well-flavoured fruit. When Strawberries have occupied a piece of ground for three years it is, I consider, sufficiently long; and when the last crop of fruit is cleared the plants may be trenched in together with heavy manuring. Such old Strawberry grounds are excellent quarters for Cauliflowers to winter under handlights; and quarters that have carried crops of early Peas or Potatoes are very suitable to be planted with Strawberries, and which afford a desirable change in the rotation of crops. All kinds of fruits in this garden were large in size, well coloured, and in most cases very free from insects. The late Pears, even after the frost of October 26, when we registered 18° of frost, were not gathered until the second week in November, yet these fruits were in no way injured by remaining hanging on the trees. I think we are, as a rule, too hasty in gathering fruit, and a large quantity of fruit, especially Pears, is picked much too soon, and because we fear the frost. Marie Louise Pears were in use for dessert throughout the greater part of the month of December, and I have only just now (January 20) finished using a lot of fine Glou Morceau: Winter Nelis and Josephine de Malines have been excellent; Beurré Rance has ripened well with us this season, which is an unusual incident. Apples of all kinds have kept better than usual, the examples of King of the Pippin and Blenheim Orange have been preserved up to within the last few days. Cox's Orange Pippin is the variety now in best condition for dessert purposes, and among other later varieties that are keeping well are Dumelow's Seedling, Annie Elizabeth, and Northern Greening. *Edward Ward, Hewell, Bromsgrove.*

EXHIBITION FUCHSIAS.—What is wanted in exhibition Fuchsias is quick free-growing varieties that will bear stopping, and soon put forth a fresh growth; a symmetrical habit, or, I might say, a free habit that will admit of the plant being grown to almost any shape, and a generous freedom and continuity of bloom. I have seen some Fuchsias that seemed to exhaust their floriferous quality at one time of blooming; others will go on flowering for weeks. It is this type that Mr. Lye, of Clyffe Hall, has so persistently worked for; and the fact that the varieties he has raised are so markedly coming to the fore as exhibition plants in many parts of the country is the best proof of their adaptability for this purpose. Mr. Lye is too sensible a man to boast of his productions; but in writing to him a few days ago, I asked him to give me a list of the very best fifteen varieties he has raised for exhibition purposes. In reply he forwards such a list, and he does not hesitate to say, "I would not mind showing the following Fuchsias against any varieties sent out; but some of my new ones of this year will surpass many in the following lists:—Dark varieties: Abundance, extra good; Charming, Elegance, Final, Hon. Mrs. Hay, James Welch, Lye's Rival, and Thomas King. Light varieties: Annie Earl, Beauty of the West, Favourite, Harriet Lye, Mrs. James Glass, Pink Perfection, and Surprise, extra good." I have seen most of these exhibited at Bath, Trowbridge, &c., and can bear testimony to their high quality. *R. D.*

SOCIETIES.

LINNEAN.

FEBRUARY 2.—Mr. Carruthers, F.R.S., President, in the chair. Dr. William Schlich, Mr. Isaac Thompson, and Mr. W. S. McMillan were formally admitted Fellows of the Society. The President called attention to the loss which the Society had sustained by the deaths of Professor Asa Gray, Professor Anton de Bary, and Dr. Boswell (formerly Syme), which had occurred since the date of the last meeting, and gave a brief review of the life and labours of each. Mr. C. T. Drury exhibited a collection of abnormal British Ferns, and made some remarks on the extraordinary number of named varieties which had been recognised, and which now

required to be carefully examined and compared with a view to some systematic arrangement of them. A discussion followed in which the President, Mr. J. G. Baker, F.R.S., Dr. Murie, and others, took part. Dr. Amadeo exhibited and made some observations on a new species of *Tabernaemontana*. A long and interesting paper was then read by Mr. Henry T. Blanford, F.R.S., on the "Ferns of Simla, based upon a collection which he had himself made there, not much below 4500 feet, nor above 10,500 feet." His remarks were illustrated by a map, and by the exhibition of a number of the more noticeable Ferns collected, many of which were extremely beautiful. Criticisms were offered by Mr. C. B. Clarke, F.R.S., Mr. Gamble (Conservator of Forests, Northern Circle, Madras), and Dr. William Schlich (Inspector-General of Forests to the Government of India). A paper was then read by Mr. H. J. Veitch, F.L.S., on the "Fertilisation of *Cattleya labiata* var. *Mossie*," in which he detailed the results of experiments he had made, illustrating the various stages by a series of delicate drawings executed by Mr. Berjean, several of which were enlarged and treated diagrammatically for the better explanation of the observations made. A discussion followed, in which Mr. H. N. Ridley, Mr. Baker, and others took part, and to their inquiries for further particulars Mr. Veitch replied. The next paper, by Mr. Joseph S. Baly, F.L.S., contained descriptions of new species of *Galerucina*, and being of a technical nature was taken as read. The meeting then adjourned to February 16.

TORQUAY HORTICULTURAL.

We print from the *Torquay Directory* a most useful proposition concerning sick and needy gardeners, made by Messrs. Curtis, Sandford & Co., Devon Roseries, Torquay:—

For some years past the Torquay Horticultural Society has fallen upon evil times. What with bad weather at the exhibitions and a falling off of contributors, it has had great difficulty in keeping afloat. The last year was especially disastrous, and has landed the Society in a considerable debt. Originally the Society contented itself with an annual exhibition in the summer, usually held in a marquee in the Public Gardens. Of late years spring and autumn exhibitions have been added—with, of course, a corresponding expense. It should be mentioned, however, that the spring and autumn shows are self-supporting—that is to say, that the income just meets the expenditure. Curiously enough, the actual loss is incurred by the summer show, which really ought to be the most remunerative of the whole. But such is the case, and the members, at the annual meeting on Friday, resolved to discontinue the summer display. If, however, persons are inclined to come forward and guarantee the expenses, the Society will no doubt see its way clear to revising the decision it has arrived at. In connection with this matter, Messrs. Curtis, Sandford & Co., of the Devon Rosery, have sent us the following letter.

A ROSE-DAY FOR TORQUAY.

"Sir,—We very much regret the necessity which our Horticultural Society wisely sees of abandoning the usual summer show, commonly called the Rose Show.

For ourselves we should have been very pleased to stage again, as we did last year, the best collection of Roses it was possible to cut in our rosery, exactly as if we were competing for prizes, which money we gladly gave up last year towards helping the Society out of its financial difficulty.

In consequence of the decision of the committee at their meeting held on Thursday, published in your present issue, to abandon the show, we now intend to have an exhibition of Roses at our rosery, to be held on our new premises, on either Wednesday, the 26th or 27th of June next. The exhibition will be perfectly free and open, and we shall give a welcome to every lover of the Rose; but we intend to have collecting-boxes placed among the stands towards a fund, which shall be the nucleus for helping gardeners in distress, the widows and orphans of gardeners, and to assist gardeners to emigrate from the Torbay district with their families, or to help towards the alleviation of any genuine distress among gardeners who are known to us or our friends.

We propose to accept boxes of Rose blooms from any amateur gardener who may have sufficiently good specimens for exhibition, which we should stage

in our best room, and we may be able to offer a few prizes; this, however, we have not yet decided upon.

If the plan should answer, and give pleasure to our friends and patrons, as well as a little timely assistance to our poorer brethren in the gardening profession, we shall continue (D.V.) from year to year to have a Rose day for Torquay.

Full particulars of this, our first venture, will be advertised in May next.—We are, sir, yours faithfully, *Curtis, Sandford & Co., Devon Rosery, Torquay, January 20, 1888.*"

Messrs. Curtis, Sandford & Co., we learn, intend, should funds come in, to extend a helping hand to the many gardeners, especially in the North, who, through frequent exposure to extremes of temperature from which they suffer in Orchid work, get into bad health, and to whom a change into the lovely county of Devon, and the seaside town of Torquay for a few weeks, would be a means of setting them up in health. Dr. Ramsay, of Torquay, whose generosity to gardeners is well known, will assist them in getting the use of a sanatorium here on special terms, and he would look after them medically, and they secretarially. It is thought that where the gardener is too indigent to pay the special terms for board and lodging and fare down, the medical and secretarial work would be free; and that they could, with the assistance of the man's master, pay for this necessary cost. The invalid would have comfortable rooms for a few weeks, plenty of good food, companions amongst his brother gardeners, and the sea air and breezes of Torquay.

MANCHESTER HORTICULTURAL IMPROVEMENT.

FRUITS AND FLOWERS OF THE CHANNEL ISLANDS.—Mr. E. Griffiths Hughes, of this city, read a paper on the "Fruits and Flowers of the Channel Islands" before the members of this Society at their meeting on Thursday evening, February 2. Mr. Bruce Findlay, President of the Society, was in the chair.

Mr. Hughes said the production and consumption of fruit and cultivation of flowers in England has grown within the last few years to dimensions which can hardly be realised by persons not connected with the various branches of horticulture or floriculture. Very few years ago our open markets and market halls were used for the sale of vegetables and fruits which came from the country districts during the summer months and autumn, and were principally grown in the open air, with the addition of Oranges, Apples, Pears, and other fruit imported from foreign lands. The few Grapes which were seen were imported and poor in quality. The flowers consisted of a few English-grown Roses not especially cultivated for sale, but were brought by the market gardener from a superabundance of crop which were produced by attention paid to the trees from a natural love for this particular flower inherited from his father and grandfather. This state of things is now wonderfully changed. Eatable fruit of every description is produced in every part of the county, and not only the kinds which our variable climate will permit to be grown out-of-doors, but large areas are covered with glass for the production of such fruit as were not thought of a few years ago, but which are now supplied in large quantities, and sold in the ordinary way of trade. The same remark applies to flowers, the sale of which grows in proportion as the numerous uses which the fashion and tastes of the people are enlarged by an appreciation of them. The introduction of steam and quick travelling has brought within easy reach fruit and flowers from the Channel Islands, and they are brought to our market day by day as fresh and beautiful as if gathered from our own gardens the day before. I will now give you an account of a visit I paid in the month of June to these charming islands, for the purpose of learning for myself the system adopted in the cultivation of fruits and flowers, and the local peculiarities which make the islands fruit and flower-producing places beyond any other from which we receive our supplies.

St. Helier, Jersey, is the port from which all the produce from the island is shipped, most of it to England. The St. Helier of fifty years ago is fast disappearing, the mania for improvements, and the conversion of what is looked upon as the reminiscences of past generations into something new, has taken a strong hold upon the people of the whole island. When one sees beautiful avenues of trees and thousands of old fruit trees destroyed for the purpose

of satisfying the greed of the people, and large tracts of land which once nourished the Apple and Pear trees, adding so much to the delight of the visitors and the pride of the inhabitants, converted into the picturesque, one may well say that a great change has taken place. From what I could gather, this demolition is likely to be carried on to a still greater extent, so that before long the whole island is likely to be converted into a vast Potato garden, in order to meet the requirements of the English markets. The extent of the Potato industry can scarcely be recognised by those who have never visited the island, and not even by the visitor unless he happens to be there when the gathering is in full swing, about the beginning of June. Last year the growers obtained over half a million sterling for Potatoes. Add to this amount the commission of the middleman and the profit of the retailer, and last year's crop could not have been consumed for much less than a million sterling. The cultivation of Grapes and Tomatoes is increasing greatly in Jersey. I have not been able to get at the exact quantities exported last year, but the quantity of Tomatoes has risen within the last six years from nil to hundreds of tons in a season. Apples and Pears which were formerly exported in large quantities have had to give place to the more profitable productions, and before very long will vanish altogether from the island. Strawberries and Raspberries are not cultivated for export purposes, the difficulty attending the packing of soft fruit being detrimental to them. They are, however, cultivated for home use, and in the dry and warm climate form very acceptable delicacies to visitors. The island of Guernsey is the very paradise of wild and cultivated flowers. The Violet and Fuchsia are almost in perpetual bloom, subtropical plants are interspersed amongst the natural flora of the island, and grow vigorously in the open grounds. The cultivation of flowers for the English market is carried on to an extent inconceivable except to those who have a knowledge of the resources of the island. The flowers exported in large quantities from Guernsey consist of Primroses, Stocks, Gladioli, Wallflowers, Pinks, Chrysanthemums, Anemones, Snowdrops, Narcissus, Tea-scented Roses, and many others. Several of the kinds of flowers are exported in such large quantities that the packages are numbered by thousands, and the Board of Trade returns show that the exports of flowers alone from the Channel Islands to England number over 30,000 baskets. I feel sure that there are many nooks and corners in England, sheltered from the north and east winds by hills, which, if covered with glass and secured by intelligent and practical gardeners as allotments of their own, under favourable circumstances, could be made highly remunerative, and in the aggregate be productive of large revenues. They would also give employment to thousands of men, women, and children in producing supplies for our markets, instead, as at present, and probably for some time to come, of importing them from abroad. *Manchester City Press.*

ENQUIRIES.

"He that questioneth much shall learn much."—BAOON.

SUITABLE PLANTS FOR THE ROCKY MOUNTAINS.—*Rocky Mountains* would be glad if any reader of the *Gardeners' Chronicle* could tell him what plants, such as vegetables, fruit trees or shrubs, or other useful perennials, would be likely to succeed on his ranche, which is situated on the lower hills of the "Rockies," about sixteen miles south of Calgary, on the Canadian Pacific Railway, about 3200 feet above the sea. Only grass and a few Cotton-wood trees (*Populus*), grow there naturally; Oats ripen well. The latitude is about the same as London, but the thermometer goes down sometimes in the winter to 50° below zero.

FIELD MICE.—A very troublesome pest—the result, no doubt, of the dry summer and warm autumn of last year—is now bothering us considerably, viz., the short-tailed field-mouse. There is scarcely anything green, or with succulent bark, but what is attacked. The depredations began in the autumn with some late Grapes, bunch after bunch of which was destroyed, in spite of all precaution. We set all sorts of traps, poisoned berries, both on the bunches and on the borders, and at length we were obliged to cover the bunches, or no doubt the vermin would have destroyed the whole. When dessert was not forthcoming the little marauders began on a

patch of late Broccoli, many of which they ate up entirely with the exception of the leaves; others they just cut off level with the ground. They have since attacked, in turn, Lettuces, bedding Calceolarias, Holly bushes, Cinerarias, and Chrysanthemums. We have destroyed scores, but the surrounding grassland furnishes an endless stream of recruits, and "still they come." I am particularly exercised about sowing the larger sorts of seeds—Peas, Beans, &c.,—as I am confident they will attack them. We have generally kept them off with paraffin and red-lead, but I am afraid this remedy will fail. Can any one suggest a better? *West Cheshire.*

NOTICES TO CORRESPONDENTS.

ANTHURUM SCHERZERIANUM: *D. E. C.* If the plant has begun to show signs of growth it can be potted, or, better, put in a deep pan or broad shallow tub, making use of rough fibrous peat and sphagnum moss. Keep the ball of roots rather high in the pan or tub, and be sure that the drainage is good. During the period of growth it requires a high temperature, with considerable moisture in the air and at the root, but during the resting-period much less water should be afforded it, and the temperature of a warm greenhouse will be found more suitable than that of the stove. A thin shading must be employed during bright weather, to preserve the foliage and flowers from injury.

BIRDS EATING CARNATIONS: *H. H.* Try suspended threads with small feathers attached, or keep a bird scarer about in the garden early and late.

CATTELEYA CITRINA: *J. H. S.* When the flowers open the foliage should be found on the pseudobulbs which flower. It is, like other Cattleyas, an evergreen species, under ordinary treatment, *i.e.*, only those pseudobulbs of more than three years old have no leaves. The temperature mentioned is sufficiently high for the season.

DIPLODENIAS: *D. E. C.* See this week's "Plants and their Culture," p. 175.

DISQUALIFIED EXHIBITOR: *X. Y. Z.* The framers of the schedule are to blame, as they, instead of using the word "varieties," should have employed "kind," or "distinct species," and we think the judges erred in disqualifying you, for although you showed Cyclamen in two colours, these really made but one "kind," or "species."

FERTILISING MOSS: *A. S., Monmouth,* must send his full address before we can publish his note.

FRUITING OF THE SWEET BAY: *T. W. M.* It was due to the fine warm summer of 1887.

GRAFTING WAX: *T. D.* This can be made in different ways: the simplest is to melt beeswax in an earthen vessel, and when liquified stir into it as much mutton fat as will render it moderately pliable and free from stickiness. A little Burgundy pitch and resin may be added. This grafting wax should be used in a semi-liquid state, and should be kept warm while being used by means of a lamp.

HYACINTHS: *E. P.* The bulbs are allowed to flower, but only so far as to prove the bulbs being true to name, and they are then cut off. Hence the immense quantity of such blooms now imported into our markets in the flowering period of the Hyacinth.

INSECTS: *E. J. B., Upton Park.* The insects which have bitten off the flowering heads of the Orchids are the common *Blatta americana*, which generally swarms on board ship from the hotter parts of the New World. It has the same habits as the smaller *B. orientalis*, found in kitchens, bakehouses, &c., in great numbers, which are so difficult to get rid of.—*E. T. B.* The beetle which you discovered eating your *Dendrobium Bensoniæ* is a small imported *Longicora*, which we have never before seen, and therefore cannot refer you to any previous notice of it. It has the aspect of a native of the Eastern Islands. *I. O. W.*

LIFTING WELLINGTONIA (SEQUIA) GIGANTEUM: *J. C.* To lift trees of 20 feet in height it would be necessary to lift in one solid mass the earth containing the roots, of the weight of several tons. This can readily be done by means of a transplanting machine, such as Barron of Elvaston makes use of. The operation requires much care and experience to be successful, and is best performed after growth has begun—say late in April to July,

All coniferous trees, it should be mentioned, bear removal ill when of large size, however carefully the work may be done, they often remaining stunted and making hardly any growth for several years afterwards.

MEDLAR JELLY: *H. H.* See a letter from a correspondent on this subject on p. 180.

NAMES OF FRUIT: *H. H. Pears:* 1, Uvedale's St. Germain; 2, Old Colmar; 3, Beurré Rance; 4, Bergamotte d'Esperey.—*W. H. Apple.* Too late in the season to recognise it. Send in November or December another time.—*Stuart & Meiss.* 1, Cox's Orange Pippin; 2, Gloria Mundi; 3, Duke of Devonshire; 4, Dutch Mignonne; 5, Northern Greening.

NAMES OF PLANTS: *C. S. & Co.* 1, *Chimonanthus fragrans*; 2, *Lonicera Standishii*.—*W. Cutbush & Son.* *Leucothoe axillaris*.—*D. L. M.* *Brassia verrucosa*. The Oak is one of the evergreen sorts—probably the Fulham variety; the specimen of *Aloe vulgaris*.—*G. H.* *Cattleya Triana* var. *delicata*.—*H. R. W.* *Odontoglossum Wilckeanum*.—*J. F. P.* 1, *Croton Newmanii*; 2, *C. undulatum*; 3, *C. chrysophyllum*; 4, *Heliconia aureo-vittata*; 5, *Nepenthes Mastersiaca*, probably, but cannot say from the small specimen sent; 6, *Carex riparia variegata*.

RENEWING GORSE COVER: *S. F. & Co.* If possible the site of the covert should not cover that of the old one, but should be made on land that has not carried Gorse recently. Plough, or, better, dig the ground; and if it be poor in quality, or has no good sward that can be dug in, a heavy dressing of dung should be afforded. Harrowing, followed by sowing the seed in shallow drills 15 inches apart, or by dibbling it, afterwards rolling the land, may be done early in March. It may be necessary to thin out the plants where standing too thickly; and the land sown should be defended against the inroads of cattle and sheep by hurdles of some description. Keeping the land free from coarse weeds should be attended to at least twice a year, till the Gorse cover the ground. A good method to follow with this kind of work, and where afforestation is intended, is to let the working men in the locality have the land as allotment gardens for two years or more rent-free, or nearly so. The operations connected with taking off crops of Potatoes, Beans, Cabbage, and deep-rooting vegetables like Parsnips and Carrots, form an excellent preparation for a seed-bed, or for future planting of forest trees.

TOMATO SEED: *Henry Pain, Sydney, N. S. Wales.* The stamps and your address have been sent to the seedsman who has the seed to distribute.

TO KILL THE STUMPS OF ASH AND OTHER TIMBER TREES: *T. A. B.* Kindling fires over such roots will kill them. Drilling holes in them, and filling these with salt, is pretty effectual; but blowing them to pieces with gunpowder or dynamite is the best method, and it moreover breaks up the surrounding soil, rendering it well fitted for future cultivation.

VALLOTA: *H. T.* The base of the bulbs, and the roots, have been eaten by some creature—perhaps the grubs of a weevil or woodlouse. Examine the soil at night.

By Royal Letters Patent.—Carbon Cones.

LETHORION
 (VAPOUR CONE).

For the distribution of certain principles in a state of vapour, in Greenhouses and Conservatories, whereby their active properties are most closely brought into direct and intimate contact with vegetable productions, for the purpose of DESTROYING PARASITIC LIFE with a certainty hitherto unachieved, and without hurt or prejudice to the most delicate and fragile organization of plant life. The old system of fumigating with cloth or paper is now quite unnecessary.

Cone.	cu. feet.	PRICES.	Per case.

MESSENGER & CO.'S New CATALOGUE of Greenhouses and Heating Apparatus,

Just issued, will be found the most complete, practical, and reliable guide to all about to build, alter, or heat greenhouses. Illustrations of every description of Glass-house, from the largest range of Winter Gardens to the simplest forms of Portable Greenhouses, Plant Protectors, and Garden Frames; also of all the best kind of Boilers, Hot-water Pipes, and all appliances for heating. This Catalogue, possessing hundreds of illustrations of all the latest improvements in greenhouse building and heating, is on a scale never before attempted. It should be in the hands of every one interested in gardening, as it contains many practical hints on the subjects of which it treats, the result of many years' experience. Price 2s. post-free.

A large number of the illustrations are taken from greenhouses erected by us in various parts of the country, an inspection of this Catalogue shows, therefore, buildings the efficiency of which has been well tested by actual use. The advantages possessed by us enable us to carry out work with the utmost promptness, and in the very best style, at prices which defy competition. Surveys made and gentlemen waited on in any part of the country. Plans and Estimates free on application.

"MYTICUTTAH"

(REGISTERED).

PATENTED in GREAT BRITAIN, FRANCE and GERMANY.

As the S. M. Co.'s "Standard" Tree Pruner is admitted to be the best Pruner for work a distance from the ground, so will the two "MYTICUTTAHS" prove the handiest and most powerful for Pruning and Trimming close to the ground, such as the removal of shoots from roots of trees; also Shrubs, Fruit and Flower Bushes, Vines, and other climbing plants, &c. Their construction enables prickly Shrubs and Bushes to be Pruned without lacerating the hands or wrists, even if gloves are not worn. They will with ease cut the hardest wood growing without injuring the part left by splitting and drawing the sap several inches up and causing decay, as other implements are known to do.

For Illustrated PRICE LISTS of above and other NOVELTIES in PRUNING TOOLS, FRUIT and FLOWER GATHERERS, &c., apply to the

STANDARD MANUFACTURING COMPANY,
ST. ALKMUND'S CHURCHYARD, DERBY;

Or to their Agents, the Principal Ironmongers and Seedsmen at home and abroad.

Large size. Price in box, 9/6 Post-free 7 1/2d. extra. Length 21 inches, weight 21lb. Will cut a branch over an inch in diam.

COVENT GARDEN CLUB.

AN INAUGURAL MEETING of the above Club was held at the "Covent Garden Hotel," Southampton Street, on Monday, the 13th instant, having been convened by Mr. W. ARTHUR BOARD, at the instance of several of the principal Salesmen in Covent Garden Market, for the purpose of Forming a Club for the promotion of unity and goodfellowship amongst the Salesmen and Residents in the neighbourhood.

A Committee was formed for carrying out the necessary arrangements, and the Meeting adjourned until 8 P.M. on MONDAY NEXT, the 20th inst., when the Secretary will announce what arrangements have been made.

Salesmen and others are cordially invited to attend the Adjourned Meeting.

W. ARTHUR BOARD, Hon. Secretary.

W. H. CULLINGFORD, Esq., 198, Cromwell Road, South Kensington, S.W., February 13, 1888.

"I am greatly obliged for your Catalogue, which is not only a very interesting volume, but is a masterpiece of skill, industry, and knowledge."

J. BIDENCOPE, Esq., Hohart, Tasmania, December 23, 1887.

"The Roses reached me in magnificent order, and everything to be desired. They are of splendid growth, and arrived in the middle of summer."

"Melbourne Leader," September 3, 1887.

"We are in receipt of twenty varieties of Hybrid Primroses from Mr. Thomas Pennafether, Elsternwick, who raised them from seed received from Messrs. Cannell & Sons. The strain is known as the Beaconsfield Primroses. The flowers are exceedingly beautiful, and, owing to their being from a cross between the Polyanthus and the Primrose, most of them are variegated with two or three colours, some showing their Primrose and others the Polyanthus nigris; many of the latter being of exceedingly rich colours, while one in particular is as finely laced as any florist's flower."

CATALOGUE SENT FREE.

CATALOGUES ON APPLICATION.

CHRYSANTHEMUMS, HARDY PERENNIALS, FLORISTS' FLOWERS, and other Catalogues.

I have very much pleasure in announcing that my New Catalogues of the above and other plants are now ready, are being issued to my regular customers, and may be had post-free upon application.

HARDY PERENNIALS.

The present season's edition of this Catalogue has been prepared with an unusual amount of care, and contains almost every known Hardy Perennial of really sterling worth, either as a plant adapted specially for cutting, or as a decorative subject in pots, in the borders, or in beds, and must certainly be admitted to be the most complete Catalogue of Perennials ever published. It is embellished with a number of thoroughly well executed engravings representing many of the specially meritorious and new plants; several of the engravings have been expressly prepared for the work in question. It also contains very complete collections of

HARDY ORCHIDS, AQUATICS,
AND BOG PLANTS,
GAILLARDIAS, SUNFLOWERS,
POPPIES, IRIS, LILIES.
BAMBOOS, ETC.,
PÆONIES—TREE AND HERBACEOUS.

These are offered in a separate Catalogue, and go to constitute one of the most complete Collections of these really interesting and practically indispensable flowering plants ever offered. I was awarded, last season, several FIRST-CLASS CERTIFICATES for new varieties.

HARDY FLORISTS' FLOWERS.

This Catalogue is one of the most complete and correct of its kind containing every variety of real merit, including Carnations, Picotees, Delphiniums, Pansies, Pyrethrums, Floxes, Bostons, and several other families. Twelve pages of *Novelties* belonging to the families enumerated are also included. The Catalogue is thoroughly complete, well illustrated, and contains abundant cultural notes.

CHRYSANTHEMUMS.

My collection of this family is one of the most complete in Europe. Every variety which is really worthy of cultivation is included. Many varieties are offered in some catalogues which are really valueless; they will not be found in the Catalogue referred to. It extends to twenty pages of really first-class sorts, all fully and correctly described, and is accompanied by a well executed litho of a new, late-flowering, golden-yellow variety, named

GOVERNOR OF GUERNSEY,

which I have much pleasure in offering this season for the first time, and which I am sure is destined to become the most popular of late-flowering varieties for cutting or for decoration.

HARDY CLIMBERS

are grown at Tottenham upon a most extensive scale. My sales of this section reach prodigious proportions. Large quantities of Ampelopsis, Jasmines, Clematis, Wistarias, &c., are grown.

HARDY FERNS.

My collection of these has recently been very considerably extended, and now can fairly claim to be a complete and representative one of Hardy British and American Ferns, and is a Catalogue well deserving of the attention of all who are interested in this useful class of plants.

HARDY PRIMULAS.

I hold a very extensive collection of these, which includes every variety claiming any real usefulness, amongst which are many beautiful India and other forms.

Copies of any of the above CATALOGUES may be had upon application.

TOTTENHAM, LONDON.

1888.

WRENCH'S

SPECIALTIES of the SEASON.

BEAN—

WRENCH'S GIGANTIC RUNNER.

Pod perfectly straight, and of extraordinary length. Unrivalled for exhibition purposes. Tender and delicious. Proved last season to be unequalled.

Per Pint, 3s.; per Quart, 5s.

BORECOLE—

WRENCH'S VARIEGATED KALE.

Extra selected. Per Packet, 1s.

BROCCOLI—

SNOW'S WINTER WHITE.

A perfect stock of this unique variety. Per Packet, 1s.

WRENCH'S JANUARY SELF-PROTECTING. Per Packet, 1s.

BRUSSELS SPROUTS

WRENCH'S "KING of the MARKET."

The largest, most prolific, and most delicate flavoured of all.

Per Ounce, 1s.

CABBAGE—

WRENCH'S NEW DWARF, "THE PIGMY."

The earliest and dwarfest variety in cultivation. Admirable for private gardens.

Per Packet, 1s.

CARROT—

WRENCH'S NEW IMPROVED HORN.

A very quick grower, and very massive in shape. Flesh very delicate and without core. Seed very scarce.

Per Ounce, 1s.

WRENCH'S NEW MAIN CROP.

This splendid intermediate variety is somewhat longer than Nantes, and thicker at the shoulder, producing an enormous weight per acre.

Per Ounce, 1s.; less by the Pound.

LEEK—

THE LYON.

A regular prizetaker. Per Ounce, 1s. 6d.

PARSLEY—

WRENCH'S CHAMPION.

The finest stock in the world.

Per Ounce, 6d.

To be had Retail of all Respectable Seedsmen throughout the world,

and WHOLESALE ONLY of

JACOB WRENCH & SONS,

39, KING WILLIAM STREET,
LONDON BRIDGE, LONDON, E.C.

B.S. WILLIAMS'
SPECIALTIES IN VEGETABLE SEEDS
For 1888.

WILLIAMS' EARLY GEM PEA.

Per Quart, 2s. 9d.
The best dwarf Pea.

EMPEROR of the MARROW PEA.
Per Quart, 2s. 6d.
Very superior and well-known variety.

WILLIAMS' HAMSTEAD PARK SEEDLING (NEW) MELON.
Per Packet, 2s. 6d.

NOWTON COURT MELON (New). Per Packet, 1s. 6d.
SEMPER FIDELIS MELON (New). Per Packet, 1s. 6d.

WILLIAMS' EARLY PROLIFIC DWARF FRENCH BEAN.
Per Quart, 2s. 6d.

Acknowledged by every one to be the earliest and best French Bean in commerce.

WILLIAMS' MAGNUM BONUM ONION.
Per Packet, 1s. 6d.

The largest and best keeping Onion ever sent out.

WILLIAMS' MATCHLESS RED CELERY.
Per Packet, 1s.
The finest flavoured variety and longest keeper, largely grown for market.

MATCHLESS WHITE CELERY.
Per Packet, 1s.
The earliest and best White Celery.

WILLIAMS' IMPROVED DWARF BRUSSELS SPROUTS.
Per Packet, 1s.

Very prolific, compact, and of splendid flavour.

WILLIAMS' TELEGRAPH CUCUMBER (Woolley's Variety).
Per Packet, 1s. 6d.
Specially selected stock, best for general purposes.

TELEGRAPH CUCUMBER (Rollisson's Variety).
Per Packet, 1s. 6d.
Seed saved from a splendid stock.

Illustrated Seed CATALOGUE Gratis and Post-free on application.

VICTORIA & PARADISE

CHRISTMAS ROSE CULTURE.

INTENDING growers of Christmas Roses must be a good deal puzzled by the advice given them in the gardening papers just now. Some say, "Get your clumps with a good ball of earth about them—they will transplant easily in this way;" others say, "No; the proper way is to wash out all the soil, and divide the large plants into smaller ones, and plant them out so." One amateur states that Hellebores are indifferent to the kind of soil, and will flourish anywhere, either in sandy soil or clay; whilst another carefully prepares a border 3 feet deep with selected composts, and there plants the Hellebores, so that they can root deeply and remain undisturbed for a long time. A well-known florist gets huge plants—fifteen years old clumps—which he puts in paraffin tubs, feeds them up with manure, and thus gets masses of bloom, quite putting Orchids into the shade. Another has a stock of plants which he forces in pots one year, and then plants them out for a year, after which they are again ready, he says, for forcing. Now, which of all these is the bewildered amateur to follow? Where are the huge clumps to come from, to grow thus in tubs: and what would they cost? I well remember seeing some huge plants of Helleborus niger major in Devonshire three years ago, which I described in the Garden. The week after my communication appeared, a lady called upon the florist, and bought half-a-dozen of the largest plants: paying from 3 to 5 guineas each for them. They were taken up with huge clumps of soil, and forwarded to her ladyship's castle in Scotland, and I have often wondered since what would be the ultimate result. The same nurseryman sent me a clump, in exchange for my own variety. It weighed just a hundredweight and cost as much in carriage as it was worth; we planted it carefully, and at the end of three years it was no bigger. At the same time we took off a dozen or so of outside crowns from the large plant, and put these separately in a properly prepared border, and these bits have now grown into fine large plants. If the

whole plant had been broken up and then planted out we should now have had thirty or forty good useful plants. I should, therefore, say to the beginner—try young plants first, and when you have large ones in abundance you can force them; but do not commence with expensive large plants. Then as to soil. It is my experience that no plant requires a carefully prepared resting-place more than the Hellebore. I believe it will be found that not one-fourth of the plants sent out by the nurserymen survive the transplanting, and I think this arises mainly from unsuitable soil and environments. The green-stalked varieties (*angustifolius*) are the most difficult to grow; at the same time they are by far the best, and, therefore, most desirable. In some parts of Sale and Bagnley the nurserymen succeed with them as easily as they do with Cabbages, whilst others, a mile distant, make no progress whatever. It has been just the same with hundreds of plants sent to London nurserymen, and the cause is evidently connected with the soil. This variety seems to like a light black soil, almost peat, and to dislike clay and marl. It can, however, be suited even on such soils by a plentiful admixture of leaf-mould where peat is not available. It also is a gross feeder, and must be well mulched with manure in February and in October, when it is pushing out its new roots, and when it is forming its flower-buds. A plant that is expected to bear a hundred large flowers requires suitable food, in large measure. Depth of soil is also an essential, because the plant must never be allowed to get dry at the roots, therefore surface rooting is to be avoided, and deep rooting ensures moisture. We keep the surface of the soil deeply mulched all through the hot summer for the same reason, and thus retain as much moisture in the soil as possible. If this be well provided for, the situation is immaterial, either in sunshine or shade. For choice, I should take two-year-old plants, and transplant in February, just after the flowering and before the new rootlets begin to push forward. These, in two years, will make large plants, producing fifty or sixty blooms each. If large plants are bought in the autumn for forcing they should be got in October, and after blooming, the plants should be broken up into small plants and planted out as above. A large plant will soon dwindle away if fed up with manure and continuously forced. The largest plant I ever saw in this neighbourhood was lost the second year by over-manuring, as is almost certain to be the case.

I have a large rockery here, specially constructed for Hellebores, and nowhere do they look more beautiful, with their snowy masses of flowers, than clustered above the red sandstone. The blocks of stone are placed edgewise, so as to give about 3 feet in depth for the prepared soil, and the spaces between them are about 2 feet wide; the roots thus go straight down, and are always kept moist by the sandstone. They are overhung by evergreen foliage. In these situations they do amazingly well—better, I think, than in any other situation. *H. n. altifolius* seems also to like its roots amongst rockwork, and it is the same with the coloured Hellebores—the Lenten Roses.

I have not had a large experience of the *H. niger* major varieties, but they seem better suited to a marly soil. They are succeeding admirably with us on the Hellebore rockery, but we added a large proportion of marl to the compost in planting them. In fact we use marl largely with every Hellebore but our own, and successfully. *H. n. major* is, I consider, the best variety for general culture. Its flowers are not so large, but

there are more of them, and the good varieties, such as are grown about Bath and Exeter, are excellent. The value of Christmas Roses for funeral wreaths cannot be overrated, as they keep fresh for a fortnight when placed in the graveyards, whilst the *Encharis* and *Camellias* go brown in a couple of days. Wreaths made with Christmas Roses and Ivy are in great demand in this neighbourhood, and the cultivation by florists is increasing accordingly. Nurserymen who have stocks of Christmas Roses for sale will do well to advertise them now, stating that this is the best season for transplanting. I consider that a large proportion of the losses, as stated above, arise from transplanting just as winter is at hand. All the foreign importations are made in the autumn, and, as a rule, the beds in which they are re-planted make a very poor show the year following. Plants imported now would have a much better chance. *Wm. Brockbank, Brockhurst, Didsbury, February 10.*

NEW OR NOTEWORTHY PLANTS.

LEONTICE DARWASICA.

This is quite a new plant to cultivation, for which we are indebted to the untiring exertions of Herr Max Leichtlin, of Baden-Baden. It was discovered only recently by A. Regel in Bokhara, at an elevation of 5000—6000 feet above sea-level, and will no doubt prove as hardy as the other members of this genus grown at present in gardens. It is figured and described in the *Descriptio Plantarum Novarum et minus cognitarum*, fasc. ix., t. 14, fig. 4, where it is stated that the stalks elongate to 6 or 7 inches, terminating in a raceme of large golden-yellow flowers. In the plant in flower at Kew the tuber is about 2 inches in diameter, somewhat oval in outline, compressed, and covered with brownish scales. The stalks are congested, probably from its being grown under glass and flowering out of season; they are not more than 2 inches, bearing five to seven pretty yellow flowers, three-quarters to 1 inch in diameter. The floral leaves in two series, six in each, the outer three times larger than the inner. The bracts at the base of each flower are oval, and slightly coloured at the margins. The cauline leaves, trifoliate, are superfoliate, with a winged or auricled base, radical leaves with roundish oval leaflets, glaucous and sometimes tinted red on the margins. *D.*

CORYDALIS LEDEROURIANA.

This seems to be one of those plants that flower any time between the latter end of December and April, depending on the size, and strength of the tuber, and the mildness of the season. It is in full flower now, protected only by a square of glass, and last year, under the same conditions, it was a month later. It was found at Soongaria, North-east, Turkestan, by A. Regel, the plants in this country having been introduced through the St. Petersburg Botanic Garden. In many particulars it resembles *C. Sewerzowii*, the tuber, however, is smaller and rounder, and the flowers dark purple instead of yellow, as in that species. The radical leaves are ternately or biternately divided, ovate, and glaucous; those on the stem, are in a whorl of three each with 5—9 divisions, flowers about an inch long, spur straight or curved downwards, pale rose coloured, lobes of the corolla very striking dark purple; the raceme is from 4—6 inches long, lax flowered, with a large leafy bract at the base of each flower, glaucous-green with bright purple edges. It is a good plant for situations where it can be kept perfectly dry, underneath ledges, &c. *D.*

LÆLIA ANCEPS (Lindl.) RADIANIS, n. var.

An exceedingly fine variety. It stands near to *Lælia anceps leucosticta*. The deep purple sepals and petals have a white space at the base. The lip

is very retuse, darkest purple on the mid-lacinia and anterior border of the side-lacinia; the disc of the side-lacinia is of the darkest orange. The line-like markings are very scarce; there are three longitudinal ones and three on each side, all dark purple. It was kindly sent me by Mr. W. Bull. *H. G. Rehb. f.*

LYCASTE MACROPOGON, n. sp.*

This is much in the way of *Lycaste macrobulbon*, but its flowers are larger, and the chin is quite distinct, inasmuch as its apex is not rounded, but quite retrorse. The oblong acute sepals and the smaller, and shorter petals are orange-coloured. The lip is trifid, mid-lacinia cuneate oblong acute, hairy; side-lacinia shorter than the mid-lacinia, half oblong. A broad rhomboid callus extends from the base of the mid-lacinia to the disc between the side-lacinia; colour orange also. Column trigonous, whitish. Rostellum markedly beaked in front, covered with stiff, rather long hairs under the fovea. There are always numerous hairs on the inner base of the sepals. The bulb is very strong, oblong, acipitous, 4 inches high, 2½ broad, marked on one side with two, on the other with three longitudinal strong wrinkled ribs. It was kindly sent me by Mr. F. Sander, having been collected in Costa Rica by Mr. Hubsch. *H. G. Rehb. f.*

PHALÆNOPSIS STUARTIANA DELLA, n. var.

Messrs. H. Low & Co. have sent me a new variety of this lovely plant, *P. Stuartiana*, that some have amused themselves by calling a variety of *Phalænopsis Schilleriana*. The new variety is distinct in its linear red marks on the side-lacinia, the lip very large, purple even on the outer parts of the lateral sepals, and with large purple-chocolate blotches on the mid-lacinia of the lip. It is lovely. I may state at once with many thanks, that Messrs. H. Low & Co. have also forwarded me several flowers of *Phalænopsis denticulata*, quite like those of the first plant, so that my conscience is satisfied as to this novelty. *H. G. Rehb. f.* [We are informed by Messrs. H. Low & Co. that the *Phalænopsis* above described bloomed in the fine collection of George Firth, Esq., of Bradford. *Ed.*]

LÆLIA SUPERBIENS (Lindl.) DECORATA, n. var.

This is quite distinct from the genuine *Lælia superbiens* in its very narrow antennate sepals and petals, the very dark purple tinge of the lip, the plaited anterior parts of the keels being dark purple and in the sharp part of the keels being purple to their origin. There is very little yellow to be seen over the whole lip, whose side-lacinia are nearly covered by a dark purple very close network of dark purple veins. If you compare Mr. Bateman's or Sir William Hooker's representations you will have a very good impression of the plant, and see that very same plant which Herr Oberhofgärtner Wendland has grown and flowered for more than twenty years wonderfully well, having himself brought it from Guatemala. The variety *decorata* is a great beauty. I had it lately from Mr. F. Sander, who informs me it came originally from the celebrated collection of Mr. Dorman, The Firs, Laurie Park, Sydenham. *H. G. Rehb. f.*

ODONTOGLOSSUM + ELEGANTIUS, n. lus vel hybr. nat.

Mr. Hugh Low tells me this appears to be a hybrid between *Odontoglossum Pescatorei* and *O. Lindleyanum*. The plant very much resembles *Odontoglossum Pescatorei* in growth, and comes from Ocaña. It may rank near to *Odontoglossum Kalbreyeri* and *atauroides*. It is a pity it is none of those. Its lip is cut quite in a distinct manner, and therefore it has to have its own name with a + as it would be a mistake to assert positively what it is, as next year

* *Lycaste macropogon*, n. sp.—Aff. *L. macrobulbo*; pedunculo elongato; mento magno antrorsum angulato; sepalis oblongis acutis; tepalis brevioribus; labelli lacinis lateralis semi-oblongis, apice liberis anguste rotundatis; lacinia mediana cuneata oblonga acuta porrecta pilosula; callo depresso rhombico in basi, lacinia medianæ; columna sub fovea valde ac rigida denseque pilosa. Ex Costa Rica imp. cl. Sander. *H. G. Rehb. f.*

it may adopt a fresh disguise, though I think this quite improbable. The sepals and petals are smaller than those of a strong *Odontoglossum Lindleyanum*, lanceolate acute, sulphur coloured with brown marks, a single one on the lateral sepals. Lip trifid, side-lacinia rectangular in the middle, central lacinia cuneate oblong apiculate, with a long callus extending from the disc between the mid-lacinia and with two diverging retuse emarginate shanks at the base of the mid-lacinia. The colour is the same as the sepals, as also is that of the column. Column angled in the centre, with two small apicular acute wings. *H. G. Rehb. f.*

PHALENOPSIS F. L. AMES, n. hyb.

This, the latest of Mr. Seden's productions, is an exceedingly beautiful hybrid, in the ancestry of which three distinct species have been concerned. It was raised from the original *P. amabilis* of Blume, better known in gardens as *P. grandiflora*, the pollen having been supplied by *P. intermedia* ×; now proved to be a hybrid between *P. rosea* and *P. Aphrodite* (the *P. amabilis* of gardens). The result of this combi-

ment; the side lobes are spotted at the base, above which the colour is in lines along the veins, being nearly suffused on the front half of each lobe. The crest is yellow, spotted with purple. It is thus remarkably intermediate between its two parents, and makes a decided stride back to the tendrilled section of the genus. The influence of *P. rosea* blood, however, is very apparent in the colour of the lip. It is dedicated, at the request of the Messrs. Veitch, to the Hon. F. L. Ames, of North Easton, Massachusetts, U.S.A., a liberal patron of horticulture, and the possessor of one of the finest collections of Orchids in North America. For the illustration we (fig. 32) are indebted to Messrs. Veitch, *R. A. Rolfe.*

PLANT PORTRAITS.

AZALEA INDICA LEON PYNARET, *Revue de l'Horticulture Belge*, February.

CATLEYA HARDISONI SPLENDENS, *Orchidophile*, January.

FIG. 32.—HYBRID PHALENOPSIS "F. L. AMES."

nation is the production of a decidedly striking novelty, of which Mr. Seden is justly proud. I have received a three-flowered peduncle from Messrs. Veitch, with the information that the seed was sown in September, 1882, and the plant has thus reached the flowering stage in a little over five years. The plant has now five leaves, of which the two oldest are strictly oval, and 3 inches long, the one last developed being oblong, and twice this length, while the remaining ones are intermediate in character. The flowers are 2½ inches in diameter, and with the general shape of those of the mother plant, the petals being over an inch broad. Both sepals and petals are pure white, the whole of the lip being variously suffused, and marked with a peculiar reddish-purple, of a very pleasing shade. The shape of the lip is almost wholly that of the seed-parent, also the crest, while the reddish-purple tails are half an inch long; the ground colour is yellowish-white, inclining in places towards yellow—a colour also clearly derived from the mother-plant. The front lobe is striated with reddish-purple in front, and almost suffused with the same colour behind, the markings having a somewhat reticulated arrange-

A low-growing hardy shrub, bearing dimorphic foliage and a profusion of yellow flowers.

RANUNCULUS LYALLI, *Garden*, December 31, 1887, From the garden of C. A. Bartholomew, Esq., Reading, who contributes an interesting note on its cultivation.

ZEPHYRANTHES ATAMASCO, *Garden*, January 7.

HELIANTHUS MULTIFLORUS AND OTHER HYBRID SUNFLOWERS.

AMONGST the plants of which seeds are offered in exchange in the list sent from the Cambridge Botanic Garden I notice *Helianthus multiflorus*. This leads me to ask whether any one has ever raised *Helianthus multiflorus* from its own seed. I have often tried to do so, but though most of the genus ripen seeds

plentifully in England, and the seed germinates readily, I have always found the seed of *H. multiflorus* to be barren. Still, the variability of the plant would lead us to suppose, either that it has been reproduced from seed, or that the same hybrid (supposing it to be a hybrid, as I believe it to be) has been produced independently several times.

Without entering here into the vexed question of single-flowered plants passing into double-flowered without the intervention of seed, we have the curious fact, which many of your readers must have observed, that on the same clump of *H. multiflorus* we often see perfectly single and perfectly double flowers, though not on the same stem. In my garden this transition or reversion is from double to single, and the same reversion to single occurs in many plants of different genera; but it is generally gradual, the flower passing through intermediate stages of semi-doubleness. In the case of *H. multiflorus*, however, one stalk may produce quite single flowers, whilst the flowers on all the other stems continue double. Gardeners know that in *Helianthus* of this class each root-bud becomes a separate plant as soon as the shoot appears aboveground. It is, therefore, easy to understand that the reversion from double to single may be born in autumn with the bud. Such reversions are common, but a change from single to double is less common, though probable enough.

A Daffodil was sent me last spring, the divisions of the bulb, which bore a single and a double flower respectively, being enclosed in the same tunic, the double flower being a sport. Asa Gray was of opinion that *H. multiflorus* is a garden development of *H. decapetalus*. I have year after year compared all the parts of the two, and cannot be persuaded of their identity. No intermediate forms occur. But any one will find that on comparing the flowers and leaves of *H. multiflorus* with those of *H. annuus*, there are far more points of resemblance; and I have already expressed in these pages a belief that *H. multiflorus* is a hybrid of *H. annuus*, perhaps with *H. decapetalus*. Many of the perennial Sunflowers readily form hybrids, though amongst the thousands of seeds produced by them in gardens few are left to germinate spontaneously, as they are too much relished by birds of many kinds. The seed heads therefore require both artificial crossing and protecting in some way. I have found the annual species, *H. debilis*, readily produce hybrids with several of the perennial kinds, the crosses being partly annual and partly perennial. Hardly any, however, of the perennial forms I have yet raised have been worth perpetuating, and though some of the annual forms have been very fine, the seed of these has always proved barren. *C. Wolley Dod.*

ROSES.

STANDARD ROSES ON LAWNS.

HOWEVER unpopular the standard Rose may become among those cultivators of Roses who grow only to exhibit, it is quite certain that it is a style of growth well suited for small forecourt gardens. I was in a south-eastern suburb of London last summer, and walking along a road lined with good middle-class villa residences, I could not help being struck with the gay display made by standard Roses grown in a line on either side of the walk leading to the front door. It was just in the height of the Rose season, and the varieties, being generally vigorous growers (evidently they had been well selected for the purpose) there was set before the passer-by a feast of Roses for his eyes of no mean order. I have said there was every appearance the Roses had been well planted; but there is plenty of indifferent planting done, which means a short and unsatisfactory life for a standard Rose, and varieties are too often planted that are constitutionally unfit for the purpose. Then they are frequently planted in soils altogether too light, and, therefore, fatal to effectiveness and longevity. It should be remembered that forecourt gardens are generally in exposed positions, and except when they are wholly on a north aspect they are subject to

a great deal of hot sunshine. The artificial drainage required by a due observance of sanitary arrangements in a dwelling draws a great deal of moisture from the soil, and during summer, when the weather is hot and dry, frequent waterings are matters of urgent necessity. Standard Roses should therefore be planted in a rather stiff and good holding soil; if it is not there naturally, it should be placed there, and in the act of planting a wide hole should be made 18 inches deep, large enough to contain a good supply of turfy or clayey loam, mixed with manure; on this the fibry roots should be carefully spread out—some fine soil placed over them, filling up with the compost, and treading down firmly, and a stake placed against each stem. Not a few villa gardeners injure their Roses by piling up the soil about the stem in a little mound, much higher than is necessary, and at the same time good for the plants.

Some of the most satisfactory and enduring standard Roses I have seen had their roots pretty near the surface, the soil was nearly flat, sloping a little toward the stem, so that the roots could have the advantage of any rain that fell; and they were treated to a liberal mulching of manure every autumn. Standard Roses are sometimes injudiciously pruned by ignorant jobbing gardeners, who will remove the most vigorous wood and leave what is puny, instead of doing the reverse.

And now for a choice selection of red and crimson Roses. Take Charles Lefebvre, Abel Carrière, Madame Victor Verdier, Marie Rady, Jean Liabaud, and Ulrich Brunner. Shades of rose and pink contain some excellent varieties, such as Abel Grand, Edward Morren, John Hopper, La France, Madame Clemence Joigneaux, Magna Charta, and Paul Néron. Of blush and white Roses there are Captain Christy, Duchesse de Valombrosa, Boule de Neige, Madame Lacharme, and Princess Louise Victoria; Violette Bowyer might be added to the whites, though it is said to come small on a standard. And let water be freely administered in dry weather. What presents a more lamentable sight than thirsty standard Roses? *R. D.*

TEA-SCENTED ROSES IN PEACH-HOUSES.

Tea Roses do so well in unheated fruit-houses, whether the structure be devoted entirely to one kind of fruit or to more—and there are usually places not made use of where a Rose may be planted without interfering with the other occupants—that I think the most is not always made of the space in such houses. Having had the charge of a large unheated structure here for more than twenty years, I have had ample opportunities of proving that Vines, Peaches, and Roses do very well together; and if the matter be looked at from a commercial point of view, I have no hesitation in saying that the Roses which are grown upon pillars and up rafters and in odd corners have proved more profitable than the fruits.

When I first began to plant Roses in this house several friends warned me to be cautious about having too many Roses amongst the Peach trees, fearing that they might introduce greenfly and other insects, but I have not found any injurious effects from their presence. The Roses, it is true, have not been free from greenfly and mildew, but these have not extended to or been more troublesome on the Peach trees and the Vines than they have on other plants in houses in which no Roses are grown. As a proof of this I may mention that although the house is 70 feet long and 30 feet wide it has not cost a penny for fumigating materials for the past three years, the destruction of greenfly being effected with clear water vigorously applied by a garden engine.

I am aware that many houses devoted to Peach culture are not so large as mine; but one can grow Roses in small houses as well as in large ones, and I had evidence of this a year or two ago, when I called upon Mr. Vallance, the gardener at Redland Lodge, Bristol, where there is a long but narrow Peach-house, than which no better managed structure is to be found in the country. In this house

Mr. Vallance had planted Tea Roses at the front, and trained them up wire near the roof, the plants being sufficiently far apart to not seriously obstruct the light needed by the Peach trees beneath. This will show that it is possible for Peaches and Roses to be successfully grown in the same house.

When selecting varieties to plant, the positions they are to occupy should be considered, and it is not necessary to confine the selection to the Teas only, some of the Noisettes and hybrid Tea Roses being quite as suitable for adorning the pillars and rafters. The following varieties form my selection:—William Allan Richardson, Gloire de Dijon, Cheshunt Hybrid, Fortune's Yellow, Reine Marie Henriette, and Maréchal Niel; all these produce abundance of beautiful flowers every year six weeks before there are any Roses to be gathered in the open air, and this without artificial heat. Such of the Tea-scented varieties as Niphetos, Madame Falcot, Sunset, Marie van Houtte, President, Catherine Mermet, Etoile de Lyon, and Perle des Jardins will grow in any position if they get plenty of light and air, and the roots are planted in a fairly good soil.

Where there are dead walls and dark corners standards may be planted instead of dwarf plants, so as to bring the branches up to the light. In this house I find the Tea Roses of great value in the autumn when the cold weather brings scarcity in the open air, and often as late as the middle of November we are able to pick basketfuls of fine flowers. It is at such times that the pearly whiteness of Niphetos, and the delicate colouring of Catherine Mermet come out at their best; and yet beyond giving the roots a sufficiency of water, and the branches a yearly pruning, they receive but little other attention. *J. C. Clarke.*

THE USE OF STABLE MANURE IN MARKET GARDENING.

The system of market gardening pursued in the environs of Paris is, we believe, absolutely unique, and leaves far behind all the ordinary cultivators of vegetables. The subject has been most extensively treated by Professor I. Dybowski* both from a scientific and practical point of view, the following being a short abstract of the more practical part of his paper.

In consequence of the great quantity of manure produced in the stables of the omnibus companies of Paris and the chief towns of France, market gardens have been established near the capital, for which it is found profitable to pay enormous rents, for the sake of securing easy transit both for the manure and for the vegetable products when grown, but more particularly for the former.

A considerable proportion of the vegetables grown are sent off to the continental towns of the North of Europe—for instance, Berlin, Moscow, and St. Petersburg, and also to England.

Many of these gardens are worked almost wholly for exportation, some cultivators confining their attention to the growth of Melons, Cucumbers, and the like, while others devote themselves specially to Asparagus, Cauliflowers, Carrots, Lettuce, salad plants, Mushrooms, and even Radishes. These products are bought up by agents, who go to the gardens, choose the vegetables they require, cut and pack them on the spot, and send off as previously arranged to the different countries for sale and consumption.

High prices are paid, but only the choicest products are taken, that they may arrive at their destination in perfect preservation after their long journey.

THE DUNG.

The stable-dung when purchased is used, not as a manure, but as a source of heat, the object being to secure vegetables and salads, &c., "out of season," for which extra prices can be readily obtained. Summer is counted the dull season, but in winter all is bustle and activity.

* "La Culture Maraichère," *Annales Agronomiques*, June, 1887.

The products raised being "out of season," they consequently demand special conditions, it is therefore requisite to provide artificial heat by means of hotbeds, in order to mature the plants grown and bring them to quick perfection. The use of hotbeds is based on the fact that dung in heaps suitably constructed, and duly watered, will ferment; and this fermentation is accompanied by heat, whose intensity varies according to the means adopted.

The market gardeners, therefore, in their practice place the manure precisely under such conditions as enables it to ferment and act energetically. To act well the mass must be in contact with air for a certain time, accordingly in every case they let the dung get aerated by spreading it thinly on the ground; thus temporarily cooled it is collected, and stacked, when the heating again commences and with the greater intensity in proportion as the aëration has been more complete, and the dung exposed to the direct action of the air. If a bed is constructed without sufficient care having been taken to aërate the dung, it is found that second development of heat takes place but imperfectly. In order to secure the quantity of dung necessary for their work, the gardeners collect from the omnibus companies the horse-manure during the whole summer and stack it until required, when it is spread out and aërated as previously mentioned.

THE HOTBEDS.

Active work in the gardens commences about the middle of October. The operators raise the ground in the form of a shelving bed, then spread on the ground a continuous layer of the dung to be used in the construction of the hotbed. These beds are made by using in equal proportions stacked and fermented dung, with manure obtained fresh from the stables. The beds will be the hotter the more dung is used. After allowing all the mass to get suitably aërated, the cultivator mixes together, with a fork, and constructs the hotbeds of suitable size, to which they give a height of about 16 inches, covering the whole with a frame.

These hotbeds, after being covered with 6 inches of light rich earth, serve at first for planting the various vegetables which are only to occupy the soil for a short time. They comprise mostly Lettuce of a very rapid growing kind, which will be gathered about the end of December. Or they may be Radishes, sown alone or associated with other salad plants.

After the first crop is removed the frames are taken off and the hotbed demolished, as it would not give sufficient heat for a second growth. The mass is then stirred, a quantity of fresh dung is again added, and a new hotbed constructed. These are utilised by sowing alternately rows of Lettuce and Carrots. When, about February, the Lettuces are gathered for market, Cauliflower plants are set between the rows of Carrots and which remain until fit for table. The Cauliflowers are ready for market in May, and during the latter part of their growth they stand exposed, as the frames are removed in the month of April.

After the Cauliflowers and Carrots are matured and sold off, all kinds of vegetable products are grown in rapid succession without the aid of the frames. The beds are not finally demolished until the time arrives for the construction of new ones in the following October.

When the forcing operations on the beds are finally completed for the season, the dung, which is but little worse in a manurial sense—having lost scarcely anything save its heat, and about two-thirds of its bulk—is sold to the farmers to enrich their arable lands.

CONCLUSIONS.

As the various processes practised by the French market gardeners are of a high class, they certainly require a certain amount of technical skill in order to conduct them satisfactorily; in fact, the operators must be experts in the work. It is, however, somewhat remarkable that the importance of the results achieved in the production of ordinary kitchen-vegetables by the market gardeners of Paris has not

induced more English growers to follow their praiseworthy example.

Further, it appears to us that, as it is the cost of the hire for the transport of the dung which represents a considerable outlay pressing most heavily on the cultivator under glass, the practice here brought under notice might be very profitably followed by our English farmers, who would have but to pass the manure from their stables and feeding-sheds to the kitchen garden, and then, when utilised and exhausted of its heat, send it back in bulk to fertilise the fields.

By this means the ordinary farmer would get, with but little expense, all the heat from the dung for forcing purposes, for which the market gardeners of Paris pay so dearly, and the manure for future use afterwards. Besides which, with the aid of an expert to control the business, abundant work would by this means be found for many of the farm labourers during what is generally the slackest period of the year.

Little fear need be entertained of a lowering of prices by an over-stocked market, provided always that really superior vegetables are raised, for everyone knows how incomplete is the supply of good vegetables, and more especially of those of the earliest productions, in almost every provincial town of Great Britain. *John J. Willis, Harpenden.*

VARIATION IN ORCHIDS.

An interesting subject for consideration is the extraordinary difference in the various varieties of Orchids of the same species, as to form, colour of flowers, and habit, brought about by locality, or by the long distances separating varieties of the same species for many centuries. *Dendrobium Brymerianum bistrionicum* is a singular illustration of this peculiarity. This Orchid, recently noticed by Professor Reichenbach (p. 104, vol. iii.), comes from a district about 600 miles south of the habitat of the original variety. It seldom develops the bearded lip which is the great beauty of the original form, and as it frequently undergoes a process of self-fertilisation before the flower opens, the flowers do not develop properly, and the whole strength of the plant is devoted to making seed-pods. It is true that some of the growths of this variety are exceedingly like those of the *Bhamo* form, but an experienced eye will detect a slight difference, the stem of the inferior variety being more stunted and bottle-shaped. It may be a useful hint to collectors to avoid all inferior varieties, by collecting to the north of *Bhamo* only.

Dendrobium ciliatum and *D. c. breve* afford still more remarkable illustration of the influence of locality; no more extraordinary differences between two plants bearing the same flowers could be cited than exist in the case of these two plants. The former comes from Moulmein, the latter from the neighbourhood of *Thayetmyo*—about 400 miles apart. *D. ciliatum* has long stems, *D. c. breve* extremely short ones; not only is this the case, but the stems (or growths) of the two plants are totally distinct in form, although the flowers are apparently identical. The mode of flowering is quite different; the long-stemmed Moulmein plant flowers from the end of the completed growth, the *Thayetmyo* plant flowers from the new growth before completion. Not only are there these differences, but the foliage of the two plants is entirely dissimilar. It is true that the conditions under which the plants grow are quite different, the larger plant growing in a district which has threefold the rainfall which the habitat of the smaller plant enjoys; but this scarcely accounts for such extreme differences between the two plants as those noted.

Differences in the stem of *Dendrobium* of the same species widely separated are well known. In *D. heterocarpum* we have the Indian erect short-stemmed, the Ceylon long, and the Philippine variety drooping—all very distinct, but still with a family likeness. In *D. Bensonia* we have the small variety from the Arracan Hills, and the robust variety

majus, from the Karcen Hills, both very distinct. As regards colour, the most remarkable difference is in *Vanda Parishii*, from the Yenkontony Hills, and the rosy-purple variety *Marriottiana*, from the Siam frontier; but none of these plants show such differences in the form of flowers as are observed in the two varieties of *D. Brymerianum*, or such an extraordinary difference in growth as noticed in the two varieties of *D. ciliatum*. *Emeric S. Berkeley.*

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM CENANTHUM SUPERBUM ×.

A hybrid between *C. Harrisianum* and *C. insigne* Maulei. The culture of this *Cyripedium* is simple, for, like most of the hybrids, it possesses a strong constitution and is a free grower. It grows well in a temperature averaging about 60°. It likes a moist atmosphere and a rich soil, equal parts of good yellow loam and fibrous peat with sufficient sand to keep the whole porous. Like all *Cyripeds* it requires an abundant supply of water at all seasons except in the depth of winter. *Reichenbachia*, t. 38.

DENDROBIUM SUPERBIENS.

A North Australian species, which requires to be grown in great heat in an unshaded house and in an atmosphere laden with moisture. After flowering a long rest is required in a temperature of 55°–60°. The flowers remain for a long time in perfection. *Reichenbachia*, t. 39.

LELIA HARPOPHYLLA.

A native of the higher mountains of Brazil, where it grows on trees, and flowers in December and January. It succeeds best in an intermediate temperature like that of a *Cattleya*-house, choosing the coolest and shadiest part. It may be grown in pots or pans in fibrous peat, sphagnum, and potsherds. During growth plenty of water should be afforded. When the flower-spikes appear the temperature should be slightly raised. The plants should be kept drier, but not absolutely dry in winter. *Reichenbachia*.

CATTELEYA LAMATA VAR. TRIANE, SUB-VAR. ERNESTI.

The apices of the petals of this variety are marked with dark purple spots. *Reichenbachia*, t. 43.

SOBRALIA XANTHOLEUCA.

A yellow flowered Orchid, with flowers as large as those of a *Cattleya*, is a treasure no orchidist can afford to despise. The plant should be grown in the *Cattleya*-house, in a compost of fibry loam with broken charcoal and coarse sand. An ample supply of water should be given in the growing season. A light and airy position is requisite. The winter temperature need not exceed 55°–60°, while in summer the plants may be placed in the open air. *Reichenbachia*, t. 45.

LYCASTE SKINNERI.

Originally discovered by Mr. J. Linden, and introduced by Mr. Skinner, this plant is of simple culture. A winter temperature of 55°–60° is all that is needed, while in summer the plants may be placed in open-air frames having a northern exposure. Abundance of water should be given during the growing season till the flowers begin to show, when the quantity should be reduced. The plant should be well rested. The plants should be repotted in July, before commencing active growth. The best compost consists of rough thoroughly decayed leaf-mould mixed with about a third part of pulverised sheep or cow-manure. *Reichenbachia*, t. 41.

PHALANOPSIS STUARTIANA

succeeds best in a warm moist atmosphere of a temperature ranging from 65°–70° in winter, and from 75°–85° in summer. Basket culture is best for it; the basket should be suspended as near the roof as is convenient. Very little material is required in the basket—merely a small quantity of

broken potsherds and charcoal—but the roots should be surfaced with living sphagnum. After flowering (January) less water should be given, but during growth much should be given, and a maximum temperature of 85° be maintained. Free ventilation should be given, to avoid spot. *Reichenbachia*, t. 42.

ODONTOGLOSSUM + HEBRAICUM.

O. hebraicum is supposed to be a hybrid between *O. crispum* and *O. gloriosum*.

Professor Reichenbach considers *O. Andersonianum*, *Jenningsianum*, *baphicanthum*, *hebraicum*, *Brassia*, *deltoglossum*, *Leeanum*, *Ruckerianum*, as so many secondary forms of one primary type, *O. lanceans*, and attaches + to the name to indicate their doubtful character as possible varieties or subspecies. Readers must be careful not to confound this cross + with the sign of hybridity ×.

Professor Reichenbach, in the *Reichenbachia*, sub t. 37, gives the following arrangement of a series of forms distinguished one from the other with great difficulty:—

α Flowers typically white.

1. *O. + lanceans*, *Andersonianum*; flowers white, with fine dark maroon or purple-brown spots=*O. Andersonianum*, Rehb. f.

b lobatum; angles at the base of the lip well expanded = *O. Andersonianum lobatum*, Rehb. f.

2. *O. + lanceans* *Jenningsianum*; very near the preceding, with light yellow on the base of the lip and very long toothed angular wings to the column = *O. + Jenningsianum*.

b. limbosum, with yellow borders of sepals (from Mr. Charles Winn). *c. pauci-guttatum*, with very few scattered reddish spots (from Mr. Calvert).

β Flowers typically mauve and white.

3. *O. + lanceans* *Ruckerianum*; very fine, with numerous brown spots on mauve and white ground; it also occurs with a light ochre border=*O. + Ruckerianum*, Rehb. f.

γ Flowers typically yellow.

4. *O. + lanceans* *baphicanthum*; flowers sulphur-yellow, almost unspotted = *O. baphicanthum*, Rehb. f.

5. *O. + lanceans* *hebraicum*; flowers sulphur-coloured, or sulphur, with a white disc, with numerous polygonal or rounded dark brown spots, usually with one large spot on the lip and smaller ones. If the spots are linear it is *lineoligerum*. *b. aspersum* is tinged with light mauve = *O. hebraicum*, Rehb. f.; *b. lineoligerum*, Rehb. f.; and *c. aspersum*, Rehb. f.

6. *O. + lanceans* *Brassia*; nearly the same, with unusually long straight sepals and petals, and very few spots = *O. + Brassia*, Rehb. f.

7. *O. + lanceans* *deltoglossum*; lip very broad and toothletted; sepals and petals very narrow; sepals, petals, and lip light sulphur-coloured, with orange at base of the lip, with cinnamon spots and lines on the sepals and petals, and a spot on the disc of the lip = *O. deltoglossum*, Rehb. f.

8. *O. lanceans* *Leeanum*; near No. 7. Sepals and petals dark yellow, with numerous brown spots; lip spotted, narrower, far more acuminate; column very plump = *O. Leeanum*, Rehb. f.

AERIDES FIELDINGII.

This is a bold-growing evergreen species, with handsome foliage, from 10 inches to 1 foot long, about 2 inches across, and rich dark green in colour. The spikes are produced from the axils of the leaves, and vary from 1 to 3 feet in length, and the racemes are very dense. The flowers are large, white, beautifully mottled with clear, bright rose, the lips being wholly rich rose coloured. It blooms during May, June, and July, and continues in full beauty for three or four weeks. When in flower this plant should be placed upon a pedestal, or in some elevated position, in order to fully display the beauties of its long pendent racemes. We may, however, remark, *en passant*, that there are some varieties of this species which produce shorter racemes of bloom than the one we have here described.

This *Aërides* succeeds well with us when placed at the further end of the *Cattleya* (or intermediate) house, where it is grown upon the side tables, and experience proves to us that the majority of the species of *Aërides* do not require such a high temperature as is generally supposed necessary for their successful cultivation. We grow most of the different kinds of *Aërides* together in the same house, and they thrive admirably, forming robust growths, and flowering most profusely; they are treated to a fair amount of moisture during the summer, administered to them by syringing between their pots every day (on exceptionally hot days they will be benefited by slightly sprinkling their foliage with water from a fine-rosed syringe); but their roots should always be kept moist during the summer or autumn months; in winter, however, much less is requisite, but the plants must not be allowed to suffer through lack of water, as at this time they are still growing slowly, and developing their flower-spikes. During the winter months the night temperature may range between 55° and 60°, and during the day it may be allowed to rise a few degrees higher especially with sun-heat. In summer they will be found to thrive well in the same temperature as that recommended for *Cattleyas*. The best material in which to grow *Aërides* is living sphagnum moss, but the drainage must be thorough, and always kept open and free. If pots are used in their cultivation, fill them three-parts full of broken potsberds, and upon this place the sphagnum; in this moss, with the addition of a few potsberds or nodules of charcoal intermixed, the roots should be placed; if grown in hanging baskets the system should be just the same, but for the sake of decreasing the weight, the drainage material may be nearly all charcoal. *Aërides* require to be exposed to the full light during winter; in summer, however, they must be shaded during the hottest part of the day, but when the sun is not shining no shade will be necessary. The blinds for shading purposes should be made of some thin material, as heavy shading is dangerous, and tends to produce weak foliage, whereas it should be strong and robust, for in this lies the whole secret of the good cultivation of these plants; and if our directions are followed they will make vigorous rich green leaves, and flower in perfection. Two most important items in the cultivation of *Aërides* are to keep everything surrounding their roots in a sweet and clean condition, and to see that their foliage is clean and free from insects. *B. S. Williams* in "*Orchid Album*," t. 309, December, 1887.

PHALÉNOPSIS STUARTIANA.

Although one of the most recently introduced of garden *Phalénopsis* this species has attained a popularity second to none. It is easily grown, retains its leaves well, and flowers freely every winter, the flowers lasting a long time both when left on the plant and when cut and placed in water. If one had to limit himself to three kinds of *Phalénopsis* *P. Stuartiana* should certainly be one of them. A plant of it at Kew has produced an exceptionally strong spike, bearing sixty-eight flowers, but, owing to the recent heavy fogs, almost half of the flowers fell off just before opening. This plant has five leaves, each about 10 inches long, and it is growing in a basket suspended near the roof-glass in a very moist house. The leaves and habit of this species are like those of *P. Schilleriana*, and the flowers are 2 inches across, white, tinged with yellow, and thickly spotted on the sepals with reddish-brown. *W.*

FOREIGN PRODUCTS.

OPIMUM AND TOBACCO IN TEHERAN.

In an official report on the trade of Teheran, Persia, it is stated that Opium occupies the chief place amongst articles of export. The yearly crop in and around Ispahan may be estimated now at about 40,000 shahmans, equal to about 232 tons, and the planting of Opium and its getting in gives

employment to a very great part of the population. The Poppies are not cut before the beginning of June, and the juice is then brought to the market in copper vessels. As a rule Opium changes hands twice, and even oftener before it comes into the hands of the exporter, and varies very much in quality, according to the soil in which it is grown, one of the most renowned districts being the village of Kupa, at a short distance east of Ispahan. London and Hong Kong are the chief customers, and the merchants prepare it according to the wants of those markets. Of late years the planting of Opium has more and more encroached on the grounds available for cultivation, owing to its yielding heavier profits to the cultivator than corn and other cereals. The quality of Ispahan Opium is now much appreciated in foreign markets, and more attention is being paid to its preparation than formerly. The annual exportation is now about 2500 cases of 10 to 11 shahmans each, which at an average price of 200 tomans, gives the respectable total of 500,000 tomans—about £170,000. Of course prices vary very much according to supply and demand.

The fluctuations in the prices are occasionally enormous. In one particular season (two or three years ago), prices rose from 17 to 25 tomans for the prepared drug, which means about 9 to 13 tomans in the raw or unprepared state. Persian Opium now competes successfully with other descriptions (Turkey, Asia Minor, &c.), in London and Hong Kong, and it is a source of great wealth to this part of Persia. From Ispahan Opium is also sent to Shiraz and Yezd, where it is mixed with the native drug grown in those parts and thence exported to India and China. About a quarter of the Ispahan Opium is exported by English firms.

Second in importance as an article of export is Tobacco. This article is grown extensively in and around Ispahan, and exported by English and Persian houses to Baghdad, Beyrouth, Aleppo, &c. It is reckoned that in an average year about 80,000 bales, of 7½ shahmans each bale, are grown in this district, of which about 60,000 bales are exported to the places above mentioned, and also about 20,000 bales to Tabreez. A certain quantity is also sent by way of Kermanshah to Baghdad. The quality of Ispahan Tobacco is inferior to that of Shiraz. Tobacco grows well in Guilan, but is not cultivated to a very large extent. It is used mostly for cigarette smoking, and not, like the Shiraz Tobacco, for the khalian or water-pipe. There is plenty of land well adapted for its cultivation were it carried out. The forests also might be a great source of wealth, as Walnut and Boxwood are the chief trees grown. Last year a Russian, representing a company, made a contract with the authorities for the monopoly of the cutting of the forests, paying for the privilege 25,000 tomans, or £8000, for two years.

THE PRODUCTION OF SUMAC IN PALERMO.

Sumac, the powdered leaves and twigs of *Rhus coriaria*, is one of the chief commercial products of Sicily. Its growth and preparation are thus described in a recent report on the trade and commerce of Sicily. During 1886 the trade in this article showed a decided increase. It is known both in the English and American markets in the form of a more or less coarse powder packed in bags of from 50 to 60 kilos. It is prepared by grinding the dried twigs and leaves. For exportation to France, the leaves and twigs are simply dried and not ground. Sumac powder serves both as a dye and as a mordant to fix other dyes, and also for tanning leather. Good Sumac contains from 30 to 40 per cent. of the dyeing or tanning principle. The shrub flourishes best in high and dry soils, and requires but little attention after first planting. The plants, when once set out, will last for a century or two. For the first three years the plants have little value, but after that time they acquire their due proportion of their peculiar qualities. The plant is a low perennial shrub with long slender leaves. The harvest consists of cutting off the leaves annually, after which the plant throws out new shoots. Sicilian Sumac, especially that about Palermo, enjoys a high reputation, as does also the Sumac

of Spain and Portugal. The soil of Dalmatia is also peculiarly fitted for this plant and the cultivation of it is fostered by the Austrian Government. The largest and most luxuriant plants do not produce the greatest amount of tannin, and even in Sicily there is great difference in the quality of the powder. Two sorts are produced in Sicily, the best is of a rich green colour and carefully sifted, it is soft to the touch, of a rather pleasant smell and a strong astringent taste. The second has these qualities in an inferior degree while its colour degenerates and takes a reddish hue. The Sumac grown in continental Italy is much inferior to the Sicilian, and has a yellowish colour tending both to green and red. None of the inferior sorts are prepared with such care as the best Sicilian, and they are known by the prevalence of unground fibres and minute chips indicative of less pains being taken in the sifting. Various adulterations are practised in preparing Sumac for market, the most obvious, that of mixing with it mineral dust, can be discerned by steeping the suspected powder in water, when the mineral portions fall to the bottom.

CULTURAL MEMORANDA.

AMARANTHUS SALICIFOLIUS VAR.

This is a very effective plant of pyramidal habit, having narrow, brilliantly-marked leaves, from 7 to 15 inches long, which by their drooping habit give the plant a very graceful appearance. The varieties, *A. s. Henderi* and *A. s. tricolor magnificus*, are among the prettiest of furnishing plants. The seeds should be sown at once in pans or pots of sifted loam and leaf-mould in about equal parts, and a little silver-sand added. Cover the seeds slightly with the compost, place the pan in a hotbed or forcing-house, and after watering cover with a piece of glass. As soon as the seedling plants are large enough they should be pricked out in a box or pan at 2 inches apart, put back in heat near to the glass and watered, potting them singly into 3-inch pots before the plants get crowded or the roots matted, afterwards shifting them into 48 and 32-sized pots, growing them on near the glass in each case, and giving more air as the season advances, and the plants near the attainment of their proper dimensions, when a free circulation of fresh air should be admitted to the structure in which they are growing during favourable weather. Three parts of light fibry loam to one of leaf-soil and sand should be used in shifting the plants into the 4½-inch and 6-inch pots respectively; and if a small percentage of the plants are kept in the 3-inch and 4½-inch pots they will be found very serviceable for associating with other plants in rooms, &c. *H. W. W.* [In warm localities and in warm spots in almost any garden these varieties of *Amaranthus* can be made to form effective groups out-of-doors. *Ed.*]

THE ARALIAS.

As decorative foliage plants some species and varieties of *Aralia* have few equals, while they are of easy culture. They require a brisk moist heat and frequent syringing to keep down insect-pests, which they are very subject to, especially scale, which latter is best removed with a moderately stiff brush. The mixture I find them to succeed best in consists of two parts good fibrous loam and one part good brown peat, with sufficient coarse sand added to make it porous, a little old Mushroom-house manure may also be added; pot in clean well drained pots, pressing the soil moderately firm. The most useful varieties are *A. Veitchii*, *A. V. gracillima*, *A. elegantissima*, *A. gracillima monstrosa*, *A. Kerchoviana*, and *A. leptophylla*. The two first-named, to grow them successfully, require to be grafted on some stronger growing kind, as *A. reticulata* or *A. monstrosa*. When grafting the stock should be shaken out of its pot, and the scion placed as low down the stock as possible. This is important, and should not be omitted. After grafting repot in sphagnum, and

place in a propagating pit until the union has taken place, afterwards potting the plant in the compost above-mentioned, completely burying the stock at the operation. The other varieties will succeed on their own roots, and are easily propagated from cuttings and sometimes from seed. *Charles Ensoll.*

LEYSWOOD.

In our issue for September 3 last we inserted an account of the beautiful gardens of J. W. Temple, Esq.

As we have so recently described the gardens at Leyswood, we need only refer now to p. 272 of our last volume, and let our illustration tell its own tale. Among the numerous Conifers which thrive in that establishment must be mentioned the beautiful specimens of *Thuia* or *Biota* Sieboldi, of which an illustration is given at p. 213. This is a form of the common Eastern Arbor-vitæ, in which the young form of leaf is preserved to adult age, the ordinary form of leaf not being produced and the whole plant forming a compact barrel, or flame-shaped bush of great symmetry and beauty and rich green colour.

the foreman in charge of them, has earned the right to be regarded as the premier hybridiser and raiser of new varieties of Primulas in the Midlands, for he was foreman at the Sparkhill Nurseries, previously noticed in the *Gardeners' Chronicle*, when the late Mr. Tomkins was the proprietor, and it was he who carefully selected and crossed from the finest of the celebrated Hayes' strain of Primulas, ultimately succeeding in producing the varieties Princess Louise and Marquis of Lorne. These two varieties were a great advance at that time, as was evident to every one, and both

FIG. 33.—THE GARDENS AT LEYSWOOD, GROOMBRIDGE.

near Groombridge. Mr. Temple has the advantage of a soft sandstone rock, which adds great picturesqueness to the garden, and affords perennial moisture and shelter to tender subjects. In the same neighbourhood the late E. W. Cooke, R.A., had a garden, the beauty and resources of which he turned to excellent account. It was his practice to probe the surface soil so as to find the fissures between the rock masses, and then to scrape away the soil so as to expose bold bluffs of rock and secure niches and valleys for tender plants, with admirable results.

NURSERY NOTES.

THE KING'S NORTON PRIMULAS.

KING'S NORTON is a short distance from Birmingham on the Midland line to Worcester, and is a famous locality for rich loam good for potting purposes and Vine borders, and here are the nurseries of Messrs. Pope & Son, in which is to be found another home of the Chinese Primula. This plant is extensively cultivated in these nurseries, and Mr. Rose,

at Sparkhill and King's Norton, many of the new varieties show their parentage by their stout foot-stalks and thick fleshy leaves, sturdy habit and the great size and substance of the flowers. Careful hybridising is still continued by Mr. Rose and a goodly lot of strong plants, many of them with very handsome foliage of a new type, are set aside for blooming for the spring flower show, and have a most promising appearance. Crosses have been made between the varieties Princess Louise and Marquis of Lorne types, and The Queen

and the finest Fern-leaved varieties, and also the seedlings of a distinctly new type of foliage.

Several specimen plants were recently to be seen in flower with massive pyramidal heads of flower, all of the Princess Louise type, and seedlings from that variety crossed with The Queen, the last-named being in every respect a splendid variety, remarkable for the size and substance of its flowers; but in these seedlings the flowers are not only large and stout, but smooth (the flowers of the Queen are not), with large, bright yellow centres. The Queen is remarkable for the great size of its flowers, which are of great substance, but have always a curled appearance. Messrs. Pope & Son have a crimson variety of The Queen, possessing all the characteristics of that variety, only that the flower is of a deep rosy-red colour, and in reality is a dark Queen. This strain of Primulas stands out conspicuously amongst all other strains, but unfortunately it is difficult to obtain much seed from them, and the demand much exceeds the supply. D.

INDIA.

ROYAL BOTANIC GARDEN, CALCUTTA.

THE annual report of the Royal Botanic Garden, Calcutta, for the year 1886-87, reached us some time since. This being the report for the hundredth year of its existence, Dr. King has taken the opportunity of giving a sketch of the history of the institution. The following extract contains an interesting account of the garden since its formation:—

The suggestion to form a botanic garden here was first made to the Government in Calcutta in June, 1767, by Colonel Robert Kyd, then Superintendent of the Honourable Company's Dockyard at Kidderpore, practical effect being given to it during the following year by the selection, as a site, of a large piece of land immediately below Colonel Kyd's private garden at Shalimar. Colonel Kyd was himself an ardent horticulturist, and he had brought together in his private garden at Shalimar a large collection of exotic plants, chiefly from the Straits. He was therefore very appropriately appointed the first Superintendent of the Botanic Garden which had been founded at his suggestion. Colonel Kyd continued to perform the duties of Superintendent until his death in 1793. On Colonel Kyd's death Government decided to put the garden under the charge of a special officer, who should have no other duty. Dr. William Roxburgh, the Company's botanist in Madras, was therefore transferred from that Presidency, and was installed at Seepore in November, 1793. Dr. Roxburgh, for many years prior to his transfer, had been engaged in studying the then little known flora of the Northern Circars in the Madras Presidency. Dr. Roxburgh continued to be Superintendent until 1814, when he was obliged to proceed to the Cape on account of his health. From the Cape he went on to St. Helena, and from thence to England, where he died during the following year. Dr. Roxburgh was the first botanist who attempted to draw up a systematic account of the plants of India. Roxburgh's *Flora*, completed by his sons after the decease of the Doctor, is the basis of all subsequent Indian botanical works, and its authorship justly entitles Roxburgh to his title of the Father of Indian Botany. A second edition of this excellent manual was issued by Mr. C. B. Clarke in 1874, at a merely nominal price. Besides the *Flora Indica*, Roxburgh published, at the expense of the Honourable Company, in three large folio volumes, his *Plante Coromandeliane*, being descriptions with figures of 300 of the most striking plants of the Coromandel Coast. Dr. Roxburgh was immediately succeeded in the Superintendency of the garden by Dr. Francis Buchanan (afterwards Hamilton), who at the time was on special duty in connection with an extended enquiry into the agriculture of India and in the collection of materials for a Gazetteer. Dr. Buchanan Hamilton held charge of the garden for only a short time, and he

was succeeded in 1817 by Dr. Nathaniel Wallich, lately surgeon to the Danish Settlement at Serampore. Dr. Wallich was an able and most energetic botanist, and during the earlier part of his term of office he organised collecting expeditions into the remote and then little known regions of Kumaon, Nepal, Silet, Tenasserim, Pensa, and Singapore. The materials (in the shape of dried specimens of plants) thus accumulated were taken by Dr. Wallich to London, and, after being named there by himself and by other botanists, they were distributed in numbered collections to the leading botanical institutions in Europe. Besides distributing these enormous collections, Dr. Wallich was enabled, through the munificence of the Honourable Company, to publish, under the title of *Plante Asiaticae Rariores*, three superb volumes, illustrated by coloured figures of a high degree of excellence. Dr. Wallich retired in 1846, and died in 1854. During the lengthened absences of Dr. Wallich in Europe his place at the garden was filled by Dr. W. Griffith, whose premature death deprived botanical science of one of its ablest and most industrious votaries. Dr. Griffith's extensive notes and numerous drawings were, after his death, published by Government in nine volumes. Dr. Wallich was succeeded by Dr. Hugh Falconer. Dr. Falconer was a palaeontologist, well known by his researches on the Sivalik fossil mammalia. In 1855 he left the country on account of ill health, and was succeeded as Superintendent by Dr. Thomas Thomson, a traveller and botanist of much ability, the coadjutor of Sir Joseph Hooker in the collection and distribution of an extensive and well-known herbarium of East Indian plants, and the joint author of the first volume of a new *Flora Indica*. Dr. Thomson retired in 1861, and was succeeded by Dr. Thomas Anderson, whose untimely death in 1870 was caused by disease contracted during his efforts for the introduction of the quinine-yielding Cinchoonas into the Sikkim Himalaya. For the two years subsequent to Dr. Anderson's departure from India Mr. C. B. Clarke acted as Superintendent, and during his incumbency he began the series of botanical publications which has earned for him so high a scientific reputation.

It was intended that the garden should not only be a botanical but also a horticultural and agricultural garden. At first great hopes were entertained that the spices which rendered the trade of the Company with the Moluccas and other of the Malayan Islands so valuable, might be cultivated in Bengal. The earliest efforts of Colonel Kyd were therefore directed to the introduction of the trees which yield Nutmegs, Cloves, and Cinnamon, and of the Pepper vines. It was, however, speedily proved that the climate of Northern India is quite unsuited to these equatorial species. The equatorial fruits, such as Mangosteen, Langsat, Dukko, and Bread-fruit, were also tried with a similar result; and so were the temperate fruits of Europe. In fact, no small part of the benefits conferred on the country by the garden in its early days was the demonstration by practical experiment that certain natural products, many of them of a most desirable kind, cannot be grown in Bengal; much money and bootless effort being thus saved to the country. The introduction of exotic timber trees also received early attention; and in the garden there still remain a few of the original Mahogany trees introduced in these early years. The introduction of Tea was one of the items put down in Colonel Kyd's original programme; and in the final establishment of what has now become one of the most important industries in Northern India, the garden bore a most important part. Potato growing was introduced through its agency, and the cultivation of the quinine-yielding Cinchoonas of the Andes was initiated and carried to a successful issue under the direction of Superintendents of this garden. In the improvement of Indian Cotton, and in the introduction both of that and of Jute to the markets of Europe, the garden authorities worked cordially hand in hand with the Agri-Horticultural Society of India, with what success it is unnecessary to point out. By the introduction of some of the best kinds of Sugar-cane

from the West Indies, and the dissemination of these to all parts of the country, a considerable improvement was effected both in the quality and quantity of the sugar crop of the country. Chief among the economic plants cultivated here are Flax, Hemp, Tobacco, Henbane, Vanilla, Coffee (Arabian and Liberian), Cocoa, Ipecacuanha, Aloes, Sarsaparilla, Jalap, Indiarubber, Cardamoms, Tapioca, and Coca. As regards horticulture, it may suffice to say that a large proportion of the kinds of exotic plants now found in private gardens in India has been introduced to the country through the agency of this garden, and that the improved methods of cultivation which now obtain were to a great extent initiated here.

In the year 1861 the garden was devastated by a cyclonic storm of extraordinary violence, which either uprooted or broke to pieces the majority of the trees in it, and, by blowing down all the plant-houses, hopelessly crushed their contents. The few trees which escaped on that occasion were sadly reduced in number by a second cyclone which passed over the garden in 1867; and, at the present time, almost the only trees dating from before 1867 are the great Banyan and a smaller tree of the same sort, some Peepals, and country Almonds, about twenty Mahogany trees, and some Palms. It is almost a pity that the occasion of its destruction by these cyclones was not taken to remove the garden to a site on the Calcutta side of the Hooghly. For, although there are certain advantages in the garden being so remote from the town, there can be little doubt that the balance is in favour of a site more easily accessible to the residents of Calcutta. The destruction of all shade, which resulted from the removal of the trees, allowed the inveterate weed known popularly as Ouloo grass, and botanically as *Imperata cylindrica*, to take possession of the whole of the ground not occupied by roads or flower borders. The liberality of the local Government, under whose control it soon thereafter passed, has made it possible for Dr. King to lay out the garden entirely anew. The whole of its area has since that date been treated for landscape effects, sheets of ornamental water having been formed, and, with the earth so obtained, undulations have been thrown up. New roads and footpaths have been made; a building for the herbarium, and three handsome conservatories for the more delicate kinds of living plants have been erected; nursery buildings have been put up, and the garden staff have been furnished with comfortable houses.

The transformation which has taken place in the aspect of the garden has been the work of Dr. King himself, whose skill, taste, and assiduity were fully recognised by Sir Ashley Eden, and supported by him with liberal grants of money. The garden is now in its scientific capacity admittedly the first of all botanical institutions in Asia, and has been designated by high authority the Kew of the East.

THE HARDY FRUIT GARDEN.

FIG TREES.—Where these are grown outdoors in the mildest localities, they should be pruned and nailed at once. In pruning, cut out as much of the old wood as can be spared, leaving a sufficient number of young shoots, so that the trees will be properly furnished with bearing wood. Do not shorten back the young shoots, for it is on the extremities of these that the fruit is borne. Should the trees have an unlimited root-run, the pruning-knife should be used very sparingly, and with great judgment, otherwise the trees will produce nothing but gross succulent wood, which will not bear fruit. When protection is given to Fig trees by covering them during the winter with mats or straw, they had better be left undisturbed for several weeks longer.

Late-Planted Fruit Trees.—All fruit trees planted against walls last autumn may now be properly nailed, as the soil about the roots will by this time have settled down. Secure the stems to the wall with tar twine and be cautious when nailing the

branches, to see that the shreds are not fastened too tightly.

Gooseberry and Currant Cuttings.—These, if not made in October, should now be made and planted. In making the cuttings select shoots in which the wood is well ripened, and with the point of the knife pick out all the buds with the exception of five at the top. When made, choose a piece of ground where the soil is rich; plant in lines, in trenches cut out with a spade, or they may be dibbled in, the rows in either case being 18 inches apart, and 9 inches between each cutting in the rows.

The Orchard.—All newly planted trees should be looked over to ascertain whether the stakes and ties are secure. Those trees that were planted in the autumn, may now be finally staked, and tied with tar twine or stout Willow twigs, placing hay or straw bands round the stems, to prevent them from being injured by the ties. The final staking of trees planted recently, had better be postponed for a few weeks. Where rabbits and hares are troublesome, the stems should be protected with bunches of Furze tied round them, or place pieces of wire-netting a few inches distant from the stem, and secure it there with stakes, or, failing these, paint them with a mixture of soot and linsed oil, 2 feet upwards from the ground. Rabbits and hares do not like this, but, as it gets worn off in a few weeks, repeated applications will be necessary. *A. Ward, Stoke Edith Gardens, Hereford.*

FLORISTS' FLOWERS.

PELARGONIUMS.

The foundation of successful culture of these plants being laid in the winter or early spring, and they should be placed where light and air can play freely around them. The next point is to tie out the growths, and also thin them out when that appears necessary. Small plants are tied best by twisting a wire round the pot under the rim, and tying down the shoots to it; when large they require sticks laid over the pots, with the ends projecting; these are tied down to the wire, and a ring of wire fastened to them, to which the shoots may be fastened; only in this way can a plant be made uniform in shape, so as to display a good head of bloom, as nearly alike as possible in every part. I am now alluding to exhibition specimens from 4 to 6 feet across. The late flowering specimens of the show and fancy groups should be repotted into their flowering-pots by the middle of February at latest. An over-rich compost will produce too many leaves in proportion to the flowers; use therefore good loam five parts, one part cow-manure, one leaf-mould and some sharp sand, with the addition of an 8-inch potful of bone-dust to each barrowload of the loam. In all cases potting soil should be mixed up a month or two before using it, and it ought to be moderately moist, and as warm at least as the soil of the plants potted. The plants intended to flower in May should have been in their flowering-pots in October; and as they are well established by this time, they will require considerable supplies of water. Seedlings that are to flower in 5 or 6-inch pots should also be well established; the object is merely to test the quality of the flowers, but to do this satisfactorily the plants must be kept clean, not too much crowded; weak liquid manure should be afforded twice a week. The specimens of large-flowered varieties, when well-rooted, will also be benefited by the same kind of stimulants. The experienced exhibitor and cultivator needs not to be told that it is necessary to place sticks to the flower-stems of the large flowered section, and that the small flowering and fancy varieties do not need such support—just a few to steady the main branches being all these require.

FUCHSIAS.

These graceful and charming plants are easily grown, but it is not every one who knows the best way to produce a fine display of bloom in July, August, and September, when the greenhouse or conservatory is mostly required to be well furnished. I do not care much for very large specimens, and only

keep about one plant of each variety to furnish cuttings.

My practice is to start the plants in a vinery or Peach-house after they have been shaken out of the pots and repotted into smaller ones. When the shoots are about 2 inches long as many as are required are taken off and put in as cuttings, which at this early season form roots readily either in a hotbed or forcing-house. When the cuttings are taken off the remaining shoots are stopped so as to form bushy specimens. I like to have one main stem with well-flowered branches from the base to the summit. To obtain this result the young shoots must be stopped three times, and this will produce a well furnished plant. Many growers will have observed that the points of the young shoots of these specimen plants will sometimes show diseased tissues, becoming black, and the small leaves in course of formation die off. This is usually caused by over-watering at the roots or too much manure in the potting soil. If it is by over-watering the plants will in time grow out of it; pinch the decayed points off, and let them start afresh. The cuttings put in now will produce flowering plants in July, August, and September, or later if necessary; I have some in flower up to the time the Chrysanthemums are placed in the houses in October. *J. Douglas,*

GOLD-LACED POLYANTHUS LORD BEAconsFIELD.

This comparatively new dark ground variety is evidently a good grower, and it is likely to be useful for exhibition purposes, as it opens out in good form and with a highly refined lacing. It is in the Cheshire Favourite style. But it is not without its faults; indeed, who can name a gold-laced Polyanthus that is faultless? Lord Beaconsfield must be caught just when the pips are newly expanded and the lacing correct. It soon goes off, becomes coarse, and the pips "quarter" or divide, which is a serious fault in the eyes of the florist. There is ample room for some good new dark-ground laced Polyanthuses, and raisers will find a wide field open in which to labour. We have Lancashire Hero, Lord Beaconsfield, Exile, Prince Regent, and Cheshire Favourite, among the black grounds; George IV., Lancer, William IV., and President, among the red grounds; but additions are made very slowly indeed. Excepting the two former no new variety has come to the fore, and these only in a partial manner. If my own plants can be taken as indicating what is at all general among growers, then I am inclined to think the gold-laced Polyanthus will bloom early. My plants are in a cold frame on a north aspect, but they are certainly much forwarder than I care to see them at this season of the year. *A. D.*

THE ORCHID HOUSES.

ANGILECUM LEONIS are showing their flower-spikes; these continue to grow well in one of the warm moist divisions. When the flowers of *Zygotetium Mackayi* and *Z. crinitum* are cut, any plants which have reached the outside of the pot and produce only weak growths in the centre can be broken up and put into better form, cutting away some of the now no longer useful back pseudobulbs. *Zygotetium* are not easily shaken free of the old compost without damage being done to their roots; they do not require repotting and dividing oftener than two or three years, when they are set in order. The species will grow very well in a compost consisting of equal parts of fibrous loam, lumps of peat, and chopped-up sphagnum moss, mixed with a quantity of new or clean crocks.

Some of the *Coleogyne*s that require additional space at the root (if not flowering) can now be potted. For such as *C. barbata*, *C. Massangeana*, and *C. asperata* (Lowii), a suitable compost may be made of two parts fibrous peat and one of sphagnum moss. The latter species enjoys plenty of heat with a moist atmosphere when making growth, but due care must be taken that no water lodges in the growth when it is in a tender state.

We have found *Oncidium splendidum* to grow best when the plant was suspended at the warm end

of the Cattleya-house; it sent up its spiket here, but the buds made but little progress until the plant was transferred to the East Indian-house for a week, where the flowers soon expanded. I think there is nothing in the appearance of the pseudobulbs and leaves of this *Oncidium* that reminds one of *O. tigrinum*, although at a certain distance the flowers do resemble that species, but on close inspection they appear more beautiful, and do not possess the strong odour of that species. *C. Woodford, Downside, Leatherhead.*

THE BULB GARDEN.

NARCISSUS BROUSSONETII.

This is one of the most interesting of Narcissus, and is a charming plant in its way. From evidence in the Cambridge Botanic Garden it does not appear to flower at all freely, and if that its be true habit it is the only circumstance against its being considered a good garden plant. The individual flowers are pure white, of delicious perfume, and not unlike a *Freesia* in form. It is of great interest, from being practically without a corona. Gay proposed that it should constitute a genus apart from *Narcissus*, but though so distinct, it certainly should not do so. It has been suggested that this plant is a hybrid, but from its appearance there seems to be no sufficient reason for the supposition, nor is it perhaps likely. It scarcely requires this hypothesis to account for the excessively reduced corona, which is very variable in the genus, or the well developed filaments. It has been described as having a two-flowered scape, which it has produced at Cambridge, and also as having a four to eight-flowered scape. Is it possible that there is more than one form? It is a native of Mogador. *R. Irwin Lynch.*

THE KITCHEN GARDEN.

ASPARAGUS BEDS.—During the dry weather the manure on the Asparagus beds should be raked over several times with a wooden rake until it is broken down fine; the beds may then be lightly forked over, deep enough to bury the manure without injuring the roots, and whenever this vegetable is grown under the old system of raised beds the edges of the beds may be banked up and made firm with the back of a spade, the alleys to be afterwards manured and dug.

Onion Quarter.—The plot of ground intended for sowing with Onions should be well worked over with forks when in a fit state to stand on, in order to get the soil well pulverised before sowing the seed. Autumn sown Onions may now be transplanted during mild weather to a piece of ground that has been heavily manured and deeply dug, and lays well to the sun; this should be trodden firm and raked before planting the Onions. One foot between the rows and 9 inches from plant to plant will be suitable distances. Shallots and Garlic may also be planted.

Jerusalem Artichokes should now be planted in drills, 6 inches deep and 3 feet between, placing the sets 2 feet apart in the drills. This vegetable is better without any manure if the ground be in fair condition, as the tubers grow very unevenly in shape when it is rich. Fresh plantations of *Seakale* and *Rhubarb* should be made if deemed advisable; *Salt's Crimson*, *Hawke's Champagne*, *Prince Albert*, and *Victoria* are some of the best varieties. *Salt's Crimson* has the finest colour of any variety when cooked, but is difficult to obtain true to name; *Hawke's Champagne* is one of the best for early forcing, and *Victoria* is a very fine late variety. The ground for *Rhubarb* and *Seakale* should be well manured and deeply trenched previously. It will be advisable after planting to cover the crowns with some rough leaf-mould or similar material in cold and exposed situations.

Hotbeds.—Seeds of Brussels Sprouts, Early Cauliflowers, and Radishes should be sown, and Capsicums or Chillies in a temperature of 65°; also Parsley and Chervil on the herb border, as soon as possible. All digging and trenching which can be undertaken should be completed before the bulk of the cropping commences. *W. H. Divers, Ketton Hall.*

Advertisers are specially requested to note, that, under no circumstances whatever, can any particular position in the paper be guaranteed for advertisements occupying less space than an entire column.

SUBSCRIBERS TO

THE GARDENERS' CHRONICLE who experience any difficulty in obtaining their Copies regularly, are particularly requested to communicate with the Publisher (in cases of delay in the delivery by post, the cover should be forwarded with complaint).

APPOINTMENTS FOR THE ENSUING WEEK.

SALES.

TUESDAY,	FEB. 21	Roses and other Plants, at the City Auction Rooms, by Messrs. Protheroe & Morris.
WEDNESDAY,	FEB. 22	Roses, Fruit Trees, Shrubs, Border Plants, &c., at Stevens' Rooms. Lilies, at Protheroe & Morris' Rooms.
THURSDAY,	FEB. 23	Imported Orchids from Mr. Sander, and 10,000 <i>Lilium anatum</i> from Japan, at Stevens' Rooms.
FRIDAY,	FEB. 24	Imported and Established Orchids, at Protheroe & Morris' Rooms.
SATURDAY,	FEB. 25	Lilies, Roses, &c., at Protheroe & Morris' Rooms.

The Royal Horticultural Society. THE annual meeting, a report of which is given in another column, passed off on the whole very satisfactorily. The chief points to be noted are the final separation from South Kensington, and the hopeful feeling arising from the spirit of peace, harmony, and co-operation which prevailed. A new habitation has been found at a moderate rental for the Society, in a convenient and easily accessible situation. This may serve very well for the present till things get a little into shape. A complete horticultural policy was once more sanctioned, and the Council empowered to carry it out as far as possible. In so doing the Council will have the aid of the outside Committee, which has been re-appointed. We need not repeat here the endless proposals which have been made in our columns and elsewhere as to what should, and what should not be done; it must suffice to say that all the Fellows seem to be now of one mind as regards general principles, and we may safely trust Council and Committee to carry out details so far as circumstances allow.

The new Council, as reconstituted on Tuesday, comprises an infusion of new members to the extent of one-half of its number, the new

"half" consisting exclusively of members of the Special Committee, so that there can be no reason to say that horticulturists' interests are not considered; indeed, what we must now call the old Council have manifested throughout great magnanimity and self-abnegation in the interests of the Society.

Hitherto the Society has taken far too limited a view of its duties and responsibilities to the public and to the State. Exhibitions, small or large, and the awards of Certificates, have all but monopolised its attention. An opportunity is now offered for the Society to rise to the level of its duties, and make itself felt as the representative of a great national interest, not of mere pleasure-seekers, nor of a relatively small number of exhibitors with their own commercial interests to serve.

These matters are legitimate enough—we have not one word to say against them; but we repeat that they ought to be only details of the Society's work, details of minor importance as compared with others. The Society has always had a fine body of friends and supporters—it has still; but the plan of campaign has been utterly inadequate, the army ill organised, ill officered, and ill led. There is now a promise of better things. Want of funds is the great obstacle, and strict financial control is an urgent necessity, but we do not doubt that funds will be forthcoming when once the Society regains the confidence of the public.

Fertilisation of *Cattleya*.

A REMARKABLE paper was lately read before the Linnean Society by Mr. HARRY VEITCH, who detailed to the Society the results of his experiments and observations, made by himself and his assistant, illustrating his remarks by excellent drawings. As the paper will probably be published hereafter, we need not now enter into the details of Mr. VEITCH's extensive series of observations. Suffice it to say, that he fertilised the flowers of a large number of *Cattleya labiata* var. *Mossie*, some with their own pollen, others with pollen from other plants of the same variety, and others again with pollen from a species of *Lælia*. By the microscopic examination of sections of the column, made at various dates after fertilisation Mr. VEITCH was enabled to trace the course of the pollen-tubes to the ovary and thence to the ovules. All this has, of course, been done before, if not in this plant, at least in other allied plants, as by MARTIN DUNCAN, SPENCER COMBOLD, and others. What has not been worked out so well before is the progressive series of changes which occur after and in consequence of fertilisation in the ovary and in the ovules. These are most interesting, and constitute a series of facts for which botanists will be thankful. One point which will surprise many people is the length of time that elapses before the pollen-tubes reach the ovule and impregnate its contents, and the variety of the changes that occur in the style and ovary and even in the ovules prior to this event.

If Mr. VEITCH can find time to prosecute this line of research we may hope that, with the materials at his disposal, and the means he has of cultivating the plants under various conditions of heat, light, and moisture, he may be able greatly to augment our knowledge of the conditions and phenomena of fertilisation. It may also be expected that some light may be cast upon the now obscure phenomena of hybridisation. We may hope to ascertain why some species refuse to hybridise, while in others the intermixture is easy. To return to the *Cattleya*,

it appears from Mr. VEITCH's paper that the impregnation of the ovules of *Cattleya labiata* var. *Mossie* under glass in the climate of London takes place from sixty to seventy-five days after the pollination of the flower, the length of time being doubtless influenced by the state of the weather during the interval, and especially by the amount of direct sunlight the plants receive—the more direct sunlight the shorter the interval, and *vice versa*.

A proportion of the ovules only are fertilised, but how great that proportion is it is not possible to determine with certainty—it is never, probably, much less than one-half; it is certain also that of the seeds which are apparently mature and good, a greater or less proportion fail to germinate.

It takes about twelve months under the same conditions to effect the maturation of the capsules, it being highly probable that during the winter months—when the temperature in which the plants are kept is comparatively low, and the amount of direct sunlight and sun-heat is at the minimum—there is a cessation of growth, which is renewed as the summer months are approached.

Now that Mr. VEITCH, certainly not the least occupied of horticulturists, has set so good an example, we may hope that others will take up this subject.

A much easier matter, and one of equal or greater importance to cultivators, is the investigation of the leaf structure. We have already indicated how varied this is in this family (see *Gardeners' Chronicle*, May 9, 1885, p. 608), and how the structure is adapted to varying conditions of light and moisture. We know of few subjects more likely to lead to interesting results than the investigation of the leaf-structure of Orchids. The chief difficulty lies in the preparation of the drawings, but after an inspection of the beautiful series prepared for Mr. VEITCH it is clear that that difficulty is by no means insuperable.

THE GARDENERS' ORPHAN FUND.—Mr. A. F. BARRON writes:—"I should feel obliged if you would kindly notice in your next issue, for the information of the Hon. Local Secretaries who may be pleased to attend, that the meetings of the Executive Committees have been fixed to be held on the last Fridays in each month (excepting March 30, which, being Good Friday, the meeting will be on the 23rd), at the "Caledonian Hotel," Adelphi, at 6 o'clock p.m. Nomination forms for the first election of six children to the benefits of the fund on July 13, are now ready, and may be obtained on application to me at the Royal Horticultural Society's Garden, Chiswick."

VEITCH'S MEMORIAL PRIZES FOR 1888.—We learn that the trustees have made the following grants of Medals and prizes for the present year:—Shropshire Horticultural Society, one Medal with £5 in money, for a collection of vegetables; Glasgow and West of Scotland, one Medal, with £5, for Roses, and one Medal with £5, for Grapes; Crystal Palace, one Medal with £5, for a collection of fruit; Hull and East Riding Chrysanthemum Society, one Medal with £5; Bath Floral, one Medal with £5.

"FLORA OF BRITISH INDIA."—The fourteenth part of this invaluable publication has just been published. It contains the greater portion of the Euphorbiaceæ, monographed by Sir JOSEPH HOOKER.

COVENT GARDEN CLUB.—A Club has been inaugurated at the Covent Garden Hotel, Southampton Street, for the benefit of the salesmen and residents in the neighbourhood. Mr. W. ARTHUR BOARD is the Hon. Secretary.

FIG. 34.—OXERA PULCHELLA: FLOWERS WHITE. (SEE P. 210.)

FOOD REFORM.—Dr. B. W. RICHARDSON, who has been lately giving a lecture on food reform to upwards of 2000 persons at the Manchester Free Trade Hall, has arranged to give a series of six lectures on "Ideal Foods," in the Memorial Hall, Farringdon Street. These meetings will take place on Friday evenings during March and April, commencing on March 2, and are likely to be of especial interest to all temperance workers and philanthropists generally, as Dr. RICHARDSON, although not a vegetarian, takes a position of entire sympathy with the non-flesh system of diet, which has lately been receiving a good deal of public attention.

READING CHRYSANTHEMUM SHOW.—This exhibition, announced for November 9 next, is unavoidably postponed until November 16, the Town Hall being required for municipal purposes on the former date.

NATIONAL CHRYSANTHEMUM SOCIETY.—A numerous attended and important meeting of the general committee of this Society took place at Anderton's Hotel, Fleet Street, E.C., on the 13th inst., Mr. R. BALLANTINE, Vice-President, in the chair. The sub-committee appointed to arrange for a provincial show and also for the revision of the Society's catalogue of Chrysanthemums, brought up valuable reports, particulars of which will be given next week; suffice it to say, that the National Society will hold an exhibition at Sheffield during the third week in November next. A floral committee of fifteen members was elected, and the dates of its meeting fixed upon. The dates of the three exhibitions at the Royal Aquarium were fixed as follows: the September show on the 12th and 13th; the November show on the 7th and 8th; and the January show in 1889, on the 9th and 10th.

HELLIWELL'S PATENT GLAZING.—The patentee of this system has been awarded the Gold Medal from the Jubilee of Railways Exhibition at Paris, 1887, for his patent system of glazing.

THE LINNEAN SOCIETY.—Mr. J. E. HARTING, who has been for some years fulfilling the duties of the zoological librarian at the Natural History Museum, South Kensington, has been appointed Librarian and Assistant-Secretary of the Linnean Society in the place of Dr. McNE, resigned.

ROSE DAY AT TORQUAY.—Messrs. CURTIS SANFORD & Co. send us a further communication on this subject (see p. 183, February II.) They now wish it to be known that, instead of what they stated in the former communication, that Dr. RAMSAY will give medical aid free in all cases; and that where the gardener is unable to pay the low charges made for board and lodging at the Sanatorium and the fare down, they could perhaps, with the aid of the man's employer, defray those costs. They continue:—"Practically the Gardeners' Royal Benevolent Society, to which we subscribe, is of no use to us locally. No gardener from this district has been placed on the funds of that excellent institution. Emigration is the remedy for the poverty from which the gardening profession suffers. If we could only persuade a few of our surplus gardeners to go out with their families it would pay us who remain to pay the costs of their emigration."

WILTS HORTICULTURAL SOCIETY.—The annual meeting of the Wilts Horticultural Society was held in the Council Chamber, Salisbury, on the 8th inst., the ex-Mayor presiding, when the report of the Society for the past year was read by the Hon. Secretary (Mr. W. H. Williams), and, making due allowance for the Jubilee subscriptions detracting somewhat from the financial position of the Society, it was considered satisfactory. The Earl of Radnor was re-elected President; Lord Heytesbury, Sir Michael Hicks-Beach, Bart., W. H. Gramshaw, Esq., H. Stevens, Esq., and — Alexander, Esq., being elected as Vice-Presidents. Mr. Williams was re-elected Hon. Secretary. In the evening over a hundred gentlemen and gardeners sat down to dinner under the presidency and vice-presidency of the Mayor (E.

Waters, Esq.) and the ex-Mayor (Fred. Griffin, Esq.) of Salisbury.

ONERA PULCHELLA.

Much interest was excited at the meeting of the Royal Horticultural Society on January 10 last by the exhibit of this beautiful semi-scandent shrub. The plant is nearly allied to *Clerodendron*, and produces dense clusters of pure white curved, funnel-shaped flowers, better to be appreciated by our illustration than by words, see fig. p. 209. The plant is a native of New Caledonia, and was shown from the gardens of Sir George McLeay by Mr. Ross, who says that it succeeds well under ordinary treatment in a warm greenhouse.

PLANT NOTES.

BROWNEA GRANDICEPS.

This requires much head-room for the display of its grandeur, a tree 20 feet high with long arching branches being more than can be accommodated in an ordinary stove. In such structures as the Palm-house at Kew, however, it can be seen at its best, and as it flowers annually when healthy it deserves all the room it gets. A large plant of it is now flowering at Kew, the heads being as massive as those of *Rhododendron*, and quite as handsome as the best of these. There are, however, a great many more flowers in a head of *Brownea* than in any *Rhododendron*, the colour being a soft rosy-red. A specimen was exhibited at the Royal Horticultural Society's Floral Committee on February 14. W.

VICTORIA REGIA.

The following account of the fine plant which was grown here last year may be of some interest to your readers. It was presented to us by A. Dixon, Esq., Cherkley Court, who told me that a friend of his living in the neighborhood of the Amazon River sent him some seeds of the finest plant he could find among 1000 acres of them, and from which he grew a plant in 1886, and from which the seed of our plant came. It was planted on March 25, and soon we were able to perceive that it was a distinct variety, differing from what we had grown before, and remarkable in many ways. The turned-up margins of the leaves in some cases measured over 7 inches; the flat portion of the largest leaf was 6 feet 9½ inches in diameter inside this outer rim. The flowers were raised on a stalk 6 or 8 inches from the water—not laid on the surface as is usual, and on the second day of opening were of a particular shade of deep purple colour, although quite white at first as usual with the plants; the leaves were more numerous, and produced with greater rapidity. There were thirty-eight flowers—the first on June 15, the last on November 26. On cleaning out the tank last week we counted 2300 seeds, a few of which had germinated; and there must have been many more in the mud which we were not able to find. *William Coomber, Royal Botanic Gardens, Regent's Park.*

PLANTS AND THEIR CULTURE.

CAMELLIA BORDERS, &c.—Where there are Camellias or other large plants planted out, see that the beds do not become too dry, particularly where the hot-water pipes are contiguous to them. Camellias are very sensitive to drought, dryness, and heat, dropping their buds when allowed to suffer from these; encourage growth with liquid manure. *Woodsias*, *Cytisus racemosus* and *C. filipes*, are all beautiful, the last is a white-flowered weeping species.

Cool Frames.—*Primulas obconica*, *capitata*, *cortusoides*, *verticillata*, *sinensis*, and the *Auriculas*, will soon be showing signs of moving, and they should be seen to in the way of potting on the first favourable opportunity. The soil best suited for them is about two-thirds of good friable loam, the other third leaf-mould, and well pulverised, with dry cow-dung and sharp sand in equal proportions. In potting remove all decayed leaves, and thoroughly clean the root-stock, bringing the soil quite up to the base of the

leaves which are left. It is better not to water them, unless it be that they have a chance to become very dry. A good plan is to plunge the pots in the frame in coal-ashes; this prevents them from becoming dry, and saves the pots from being broken by frost. Moreover, it is more congenially cool to the roots of the plants than is staging. Give air in abundance when the weather outside is clear and dry, but do not remove the sashes altogether without previously preparing the plants, as much injury might be done thereby. A foot is the proper distance to have the heads of the plants clear of the glass.

East Lothian Stocks, which were potted up in the autumn, will soon be in good form, and ought to have every attention given them in the way of airing and removing decaying leaves, &c., giving occasional waterings with liquid manure. Pot on succession plants which were sown late and have been growing in pots. These grand varieties of Stocks are much liked either as cut flowers or as pot plants in the houses, the long Hyacinth-like spikes of flowers being very pretty. The cool frames are much better by being covered up at night, and, all things considered, *Frigo Domo* will be found quite as convenient and effective a material for the purpose as could be desired. If a strip the width of the frame be fixed on a round piece of wood it can quickly be put on when required. It is better where there are fastenings, such as rings or hooks at the sides, to secure it to the frames. When not in use it should be rolled up under a board or two at the end of the frame after being dried, as it is more efficient as a warmth preserver when dry.

Miscellaneous.—Prune hard back any plants yet remaining of *Ruellia Herbertii*, *Meyenias*, *Lagerströmias*, *Casias*, *Erythrinias*, and *Antigonons*, also any winter-flowering *Begonias* of the insignis type may be cut down, putting in the best of the cuttings to strike, and throwing the old plants away. Carefully attend to the wants of *B. socotrana* until the leaves have finished their work and prepared the tuber for next season. This charming *Begonia*, when well done, amply repays any little trouble in attending to its wants. *F. Ross, Pendell Court.*

FRUITS UNDER GLASS.

PEACHES AND NECTARINES.—The trees in the early house will now be swelling their fruit rapidly; let the temperature be 55° on cold nights, and 60° on mild ones, if the fruit is required at as early a period as possible. Admit a little front air during the night when the weather will permit, but do not open the top ventilators to cause a cold current of air to pass over the tender foliage. Syringe the trees in the morning with water 10° warmer than the temperature of the house, and again at shutting-up time on bright sunny days, but during dull sunless weather this may be dispensed with, and resort may be had to the watering-can and rose. Avoid deluging the borders with water, which is certain to cause a stagnation of the atmosphere during dull weather. Plenty of humidity when the weather is bright will lead to success, but an excess, when there is a deficiency of sunlight will result in thin foliage, and the conditions will be favourable for the production of mildew. Any shoots which are growing gross should have their points pinched out, and where there is the probability of the shoots becoming crowded it is better to remove some of them at once, and allow full play of light and air. It is better not to thin the crop to the desired distances until the stoning period is over, but if the trees are in good heart, there is little danger of fruit-dropping to fear. Good healthy trees will carry a crop of fruit at 9 inches apart all over the tree.

Trees which are inclined to be gross in growth may be allowed to carry more than this, while trees in a weakly state, or in advanced age, should not be allowed to carry so many, else the fruit will be deficient in size and flavour. The inside border may now require a watering. A good dressing of Vine manure should be pricked into the surface, and a watering at a temperature of 80° to 85°; shut off the heat and avoid throwing water on the hot pipes filling the house with steam. Should greenfly appear fumigate at once, and do not allow them to obtain a lodgment. See that the temperature is not too high and that the foliage is dry prior to fumigating.

The Succession House.—The trees here will now be coming into bloom, and it will be found a good plan to remove all the worst placed and the weakest flower-buds; this will throw more strength into the others which are left. Keep the trees dry while they are in

blossom, and in the middle of each day go over them with a Pampas-grass plume; damp the border and paths every afternoon at shutting-up time if the day has been sunny.

Late Houses should now all be dressed and ready to start naturally; see that the borders are in a sufficiently moist state, and the temperature is not allowed to rise too high. The principal cause of bud-dropping is dryness at the root during winter.

Figs.—As the days lengthen—and we can reckon on more sunlight than hitherto—more moisture in the atmosphere in the shape of syringings and sprinkling the paths may be afforded. Trees which are in limited root space may receive weak manure water each time they are watered; in the case of trees which were potted in autumn none will be necessary, but a little dusting with Vine manure occasionally will be found of great benefit, as this does not cause gross growth, but is conducive to fruit production.

To prevent fruit dropping, see that the trees are never allowed to feel the pinch of dryness at the root, and any small or ill-placed fruits should be removed at once. The trees should also be disbudded, and no more shoots allowed to grow than are required for the furnishing of the trees. When four leaves are formed the points of the shoots should be removed, to induce the trees to set a second crop of fruit. A second batch of trees should now be started in a moist temperature of 50° to 55°, and they should be frequently syringed; the latest batch should be kept quiet for another month.

Cherries, Plums, &c.—These must not be over-excited until such time as they have set their fruit. Let the night temperature be 45° to 50°. When the fruit is set an advance of 5° may be given, with free use of the syringe. A sharp look out must be kept, as these subjects are very liable to attacks from green and black fly. The trees should receive a good fumigation just before the blossoms open, as a preventive, and again after the fruit is set. Admit air on all favourable opportunities, but avoid draughts.

Strawberries.—Such as are showing colour should be removed to a lower temperature, and watering with manure should be discontinued. Air on all favourable occasions should be given liberally. Successions which are swelling their fruit may be kept in a temperature of 60° to 65°; those in bloom should, however, be kept as near 55° as possible. Go over plants with a fine brush in the middle of each day, to fertilise the blooms. Remove all superfluous blooms from the trusses, also the unnecessary flower-spikes. Thin the fruits to nine or twelve to each plant. Avoid fumigating while the plants are in bloom. Introduce fresh batches of plants in houses where they can be kept near the glass, where the temperature does not exceed 50°. *W. M. Bailie, Luton Hoo Gardens.*

THE FLOWER GARDEN.

TREES AND SHRUBS.—The pruning and thinning out of deciduous trees and shrubs where necessary should be completed without delay. The recent heavy falls of snow will in many instances have caused damage to coniferous and other subjects. As soon as practicable attend to the requirements of such damaged specimens, by cutting out all splintered boughs and branches, and where necessary, stake and tie into shape again. Much damage of this nature may be prevented by prompt attention in relieving the branches of snow during heavy storms that occur, by daylight.

Indoor Work.—Advantage may be taken of bad weather to prepare the required number of labels, stakes, and pegs for various purposes. Prepare compost for potting bedding-out plants, and propagating purposes, get boxes in readiness, repairing such as require it, and see that an ample supply of clean pots are at command when wanted.

Gladiolus for flowering early in the open borders may now be potted into 5-inch pots, to be planted out at a later period. Place them in a cool house, or plunge to the rims in cocoa-fibre refuse in cold frames. This plan is to be preferred to planting the bulbs at once in the open—a practice not at all to be recommended for midland and northern counties.

Zonal Pelargonium from store pots and boxes may also be transplanted thinly into other boxes or potted off singly into 3-inch pots, preference being given for the latter if the necessary amount of space can be afforded.

Seeds.—The following seeds may be sown in heat, using a compost of finely sifted loam, peat, leaf-mould, and silver-sand, viz., *Chamepeuce Cassiniana*, *C. diacantha*, *Ricinus* in variety, *Cannabis gigantea*, *Petunias*, and single *Dahlias*. A second sowing of plants named in a previous Calendar may also be made if doubts are entertained regarding the quantity of plants likely to be obtained, and an opinion on this point ought now to be formed, as the majority of them have germinated ere this. *J. Horsefield, Heytesbury.*

VEGETABLES.

STACHYS TUBERIFERA.

I HAVE GROWN this new vegetable (which you figured and described on January 7 last) for several years, and find it is well worth extensive cultivation. It is much esteemed here as a second course vegetable, and is also a useful ingredient in the salad dish, looks well, and is very palatable as a pickle, and is a fitting companion to the breakfast Radishes. Now is an excellent time for planting, putting the sets in drills 14 inches apart, and 5 or 6 inches between the sets, in free soil, not over-manured. The yield is quite a bushel to about 16 square yards. It has much the same habit of growth as Wood Sage, and is as hardy as Knot-grass (the roots of which it much resembles). Frost seems to have no effect on the roots, and I think it will grow anywhere in these islands, and will form a welcome change to the usual vegetables in November, December, and January. It requires no coddling, and in a loose soil might be allowed to occupy the ground for years, as is sometimes done with Jerusalem Artichokes. *P. Middleton, Wymstey Gardens.*

TRADE MEMORANDUM.

ST. MICHAELS PINE-APPLES.—Recently there has been a new departure in the public sales of this article; formerly they were all sold at the Pudding Lane auction sales, but Mr. J. B. Thomas has brought about a change that, it is hoped, will benefit both growers and dealers. Before commencing his last sale of Pine-apples in the Floral Hall, Covent Garden, on Tuesday last, Mr. Thomas made the following remarks:—

"The Pine sales as held in this hall are exciting attention amongst the City merchants, and some alarm amongst the City brokers. To attack and break down a monopoly of such strength as is represented at Pudding Lane requires a great deal of pluck, energy, and perseverance, more especially when attacked single-handed; but what I did in the years of 1879 and 1880 touching American Apples and Malta Potatoes I felt I could do in the years 1887 and 1888 as to Pines. My first success was a direct saving to the growers of 1½d. per Pine in securing lower charges; the second success was to abolish the tax of 1d. per Pine hitherto levied by the monopolists at Pudding Lane upon the buyers; and, third, to secure you all your identical purchases; and, further, I may say, by offering you goods less damaged in transit, which you have repeatedly shown the appreciation of by giving me your best support.

"Now, what were the answers of the City brokers to my efforts? They abolished the tax of one penny levied upon you with a growl. One broker said 'We got it out of you as long as we could,' so that is a concession you have not to thank them for; but they are evidently hard set against the poor growers. The Dock Companies had agreed with me for a 'through rate,' which was carried out on several occasions; but at last the pressure brought to bear upon the directorates has caused the Docks to cancel this rate, because the City brokers do not object to paying the higher rates. The Dock Companies had therefore to withdraw the more favourable terms granted to me, but I need scarcely say that a change will be brought about, and their interests will suffer thereby. As they will not move to save for the

growers themselves, they ought at least not to insist on preventing those who have the will to do so.

"I am very pleased to thank all my supporters, especially those who attended my first few sales, and you must all be glad to hear of the message that has come to you from the island of St. Michaels, not in direct words, but, to my mind, in much more than words, and that is, in the form of distinct orders to the several merchants here to forward their consignments of Pine-apples to the Floral Hall for sale. The result of those orders you may all see in the gallery behind you. The Pudding Lane interest represented here is not for studying your owo, the growers', or His Grace's interest. It is simply here because their monopoly is aged and tottering, and their hold is becoming too feeble to take substantial root anywhere."

HOME CORRESPONDENCE.

Correspondents will greatly oblige by sending early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Photographs or drawings of gardens, or of remarkable plants, trees, &c., are also solicited.

PSIADIA ROTUNDIFOLIA.—This interesting plant, which you figured and described (pp. 180, 181) under the title of "The Last of its Race," is, I regret to say, not represented at Kew. It is true, as you mention, that I brought seed from St. Helena in 1883, but none of it germinated. The same result attended seed taken to Jamaica, and also some sent to Ceylon and Southern India. It is very probable, as suggested by Professor Oliver, that some of these "Cabbage trees" are sub-dioecious, and if this is true as regards the plant under notice there is little hope of perpetuating it by seminal reproduction. This view is in some measure confirmed by the fact that no plants have been raised from seed sown in the island, and also by an experiment which the late Governor Janisch carried out on the spot. The ground near and under the tree was enclosed by hurdles, and the soil broken up and carefully prepared in the hope that some few well ripened seed would fall upon it and germinate. Not a single plant was thus raised. I have only to add to your excellent description of this plant, that the flowers, which are plentifully produced in May or June, are small (½ inch diameter) and white, with a yellow centre. While on the subject of St. Helena plants I would mention that I was fortunate enough during my visit to secure good seed of *Melhania Erythroxylon* (N. O. Sterculiaceae), locally called Redwood. Strong plants, about four years old, of this are established at Kew, and also in the West Indies and Ceylon. This handsome tree is fast disappearing in St. Helena, and probably will follow the allied species (*M. melanoxylon*) the native Ebony, which has become extinct during the last forty years. The flowers of the Redwood are large, tubular (about 3 inches long), and very striking; when they first appear they are pure white, the next day they change to pink, and finally to a brownish-red as they begin to fade. Flowers in all three stages are seen on the tree at the same time. Another interesting St. Helena plant established at Kew is *Sium helenianum*, an umbelliferous plant, growing to the height of 6 to 8 feet amongst the Cabbage trees and Feras on Diana's Peak. The stems of this plant are eaten raw by the native people, and are sometimes sold in the market at Jamestown under the name of *Jelico*. *D. Morris, Assistant-Director, Royal Gardens, Kew.*

GARDENERS' ORPHAN FUND.—I am extremely pleased to see that the committee have taken up the question of money boxes, and sincerely hope great good will result therefrom. There is not the least doubt but that local secretaries will do all they possibly can to forward the movement by selecting suitable places for the boxes and collecting their contents twice a year, and if holders of boxes receive a little friendly notice of his intended visit, I guess few will be the places where he will not be required to give a receipt for at least shillings and pence, and these multiplied by hundreds (as I sincerely hope they will be) will be the means of feeding and educating many a poor orphan who otherwise would be neglected and consequently would be heavily handicapped in the struggles of life in after years. *J. H.*

STRAWBERRIES.—Mr. Lovel (p. 135) raises two very interesting questions in relation to earlier and later varieties of Strawberries. His first point—and it is an invincible one—is that earlier blooms than Black Prince or other early kinds throw would assuredly (almost) be destroyed by late frosts, hence earlier fruits would be impossible. But is there no room for improvement in the direction of more rapid maturation of the fruit after the blooms are set? That seems to be the only direction in which it is possible to hope for earlier fruits from new varieties, and it is one worthy the attention of raisers. Of course it is easy to admit that small fruits ripen earlier than large ones, but we need sorts which shall mature fine fruits more rapidly. Any good kind which shall lengthen the Strawberry season by ripening a few days earlier than our present earliest would prove a great boon to growers. How does Pauline act outdoors? Is it relatively so early as under glass? With reference to late ripeners we have here again room for considerable improvement. Mr. Lovel's experience is perhaps limited to northern districts, but in the South there is not much reason, except during colder summers, to complain that late Strawberries are exceptionally acid, indeed some of the sweetest fruits to be found, as a rule, are the very late small fruits not thought otherwise good enough for ordinary gatherings. I find that there is a growing need for such late and esteemed acid kinds as Eleanor and Elton Pine, and any good later variety would be acceptable. Even really good sweet fruits have been gathered from spring planted plants so late as September, as many gardeners can testify. We want the Strawberry season lengthened at the end as well as at the beginning. The chief difficulty here in the South is found in an exceedingly dry summer, but that is not a constant contingency. *A. D.*

VINES DURING THE PAST SEASON.—I do not know that I ever remember a year in which Vines both old and young have done so well as during the past year. Vines that have been planted eight and nine years have ripened their wood better, being much firmer, and having less pith than for some time past; especially is this the case with Duke of Buccleuch. It is an important point in the successful management of this variety to have the wood well ripened. Young Vines struck from eyes last spring are also remarkable. In the month of January about 180 Vine eyes were put into 3-inch pots, in a gentle bottom-heat of from 75°—80°, where they remained until their roots touched the sides of the pots, when they were removed to a vinery having a temperature of 65°—70° by day, with a fall of 5° by night. In a few days they were potted into 6-inch pots, and remained in the same house until they had filled their pots with roots, when they were potted into 10-inch pots. About the first week in June, having previously made a new border in one of the vineries, I planted out a dozen Vines, and without receiving the slightest check they at once grew away to the top of the house, which they reached about the beginning of August, plenty of air being given at both top and front on all favourable occasions. By the beginning of September they began to show signs of ripening their wood at the bottom of the house; abundance of air was then given both night and day, and also a little fire-heat at night. This practice was continued until the end of October, when the house was thrown open day and night, except when the weather was very cold. About the second week in January I cut the Vines down to the bottom of the rafters. With this I send for your inspection a few of the pieces of the shoots. *S. A. Woods, Osberton Gardens, Worksop, February 14.* [The shoots sent are of extraordinary strength, having a circumference of 2½ inches in some cases; buds being developed at intervals of 5—6 inches. *Ep.*]

YELLOW GREENHOUSE RHODODENDRONS.—The development of these at the Royal Exotic Nurseries, Chelsea, marks a very interesting epoch in the important work of improvement in this useful class of plants, which has been carried on here for some time past. Two distinctly yellow types have recently flowered, and they show yellow flowers and yellow stamens both—they are wholly yellow; and they are the first of what promises to be a valuable race of self yellow greenhouse Rhododendrons. The species to which the development is, to a large extent, due, is *R. Teysmanni* from Sumatra. It occurred to Mr. Heale to cross this on to some other form, and he selected Maiden's Blush, one of the best shaped flowers of the Java section, in order to get the yellow colour and good form at the same time, the latter being the seed parent. From this cross came

several seedlings, the first to bloom being Primrose, which was certificated at the last meeting of the Royal Horticultural Society; represented by large, stout, well formed flowers wholly of a decided primrose colour, borne on bold trusses. Since this was exhibited, another very fine self yellow form has blossomed, and has received the name of *Boule d'Or*. In this case *Teysmanni* was the pollen, and Lord Wolsley the seed parent, the latter being a very strong-growing variety of the Java type, one of the strongest-habited, *Teysmanni* being also a sturdy and robust grower. The foliage of *Boule d'Or* is remarkably large and bold for a greenhouse Rhododendron; the leaves measure 8 inches long by 3½ in width; there is nothing like it, and it has shown the large-leaved character from a seedling. The flowers are large, finely-formed, and of a deeper hue of colour than Primrose, and it promises to make an excellent plant for conservatory purposes. I have often thought these Rhododendrons are placed at some disadvantage by being shown in the form of seedling plants. A large number of seedlings are raised every year, and one great object is to get them into bloom as soon as possible, in order that some idea may be formed of their characters, whether they are good enough to be preserved or not; hence it is they are run up in the form of a straight stem—they become tall, and produce a truss or two of blossoms on the top. It is erroneously supposed this

FIG. 35.—*DIOTA SIEHOLDI* FOLIAGE. (See p. 205.)

represents the true habit of the plant. There can be no greater mistake in reference to this class of plants. When a variety is propagated it is by means of being grafted on a suitable stock, and then charming dwarf bushes result, as unlike the seedling plants as can well be. The greenhouse Rhododendrons, though in large demand, are not so fully appreciated as they deserve to be. I think there is a great future before them, and that they will in course of time become a most useful class of decorative plants for the warm greenhouse and conservatory. *R. D.*

JUNCTIONS OF PATHS AND ROADS.—Glancing at the article under this heading in the *Gardeners' Chronicle* of January 28 (p. 116), I soon perceived a strange familiarity with the illustrations there given, and observe that they have been shamefully pilfered from my work on *How to Lay Out a Garden*. I conclude from the text that they have been pirated by some French author, but not at all well copied; the idea of their having originated in "sunnier France" being a peculiarly amusing one. I think I may fairly ask the writer of the communication whence he obtained them, and where and by whom the book containing them was written and published. We frequently read in the newspapers of the wholesale way in which our American consins appropriate the literature of this country, but I am yet unaware that they lay violent hands on our illustrations as well; and it is obvious that, in a general way, this would be too expensive an experiment. Of course I must assume that the author of your contribution accepted them in good faith,

and fairly thought he was presenting his English readers with samples of French ideas on landscape gardening. I must, however, most strenuously demur to his dictum as to what is correct or otherwise in respect to the junctions of walks. To affirm that rectangular junctions in walks are necessarily (or at all) in bad taste is, in my judgment, a purely rash and reckless assertion, and subversive of the very highest rules of art. I am bold enough to pronounce on the contrary, that there are numberless instances in which rectangular lines denote the only possible treatment, and that these, in connection with a high-class building, are as truly natural and consistent as curved lines would be in the freest and least artificial styles of gardening. As in architecture, the advocates of Classic or Gothic types are often so wedded to their own individual preferences that they hardly admit those brethren who entertain opposite convictions to be the true exponents of art; so, in gardening, it is much to be deprecated that small and confined views, born of littleness, and nursed in a groove, should be allowed to obtain, to the exclusion of those more catholic considerations which lift art out of the region of prejudice, and take in all its wide ramifications. There is such a very important principle involved in all this that I feel more than justified in endeavouring to maintain it. If your contributor repudiates altogether the employment of straight lines in garden walks, then, I imagine, he will stand quite alone, and the question is not worth arguing about. If he asserts that curved lines should merge into straight ones, without anything to break the connection or mark the point of divergence, I distinctly join issue with him, and hold as an absolute law that straight lines, unless brought to a thorough termination, admit of no branches that do not at least start from them at right angles. *Edward Kemp, The Park, Birkenhead, January 28.* [The illustrations in question have been used in various books published by M. Rothschild of Paris, and the clichés were purchased by us from him, without any knowledge on our part, that they had originally been used in Mr. Kemp's "How to Lay Out a Garden." *Ep.*]

HYBRIDISATION.—Just one line to point out to my friend, Mr. Burbidge, that if cutting off a flower is conducive to the production of such a bud as I described, it is singular that the result should not have occurred in other cases, "not a few," where I have in like manner cut off a flower from an Iris, and that the plant in which it did occur should have been a hybrid. That was all I said. That "high cultivation" may tend to monstrosities has no bearing on what I said, viz., that a hybrid seemed to me, on the whole, more liable to malformation than a plant not a hybrid; this does not mean that hybridisation is more potent in producing monsters than is cultivation; but it can, if desired, be put in the form that "cultivation is more likely to produce monsters among hybrids than among plants not hybrids." Lastly, "converted" or "altered" is not the same as "diminished" restricted vegetative energy. *M. Foster.*

FIELD MICE IN GARDENS (see p. 184).—Of the three kinds of field mice common in country gardens, the field vole, or short-tailed field mouse, is by far the worst: 1st, because it is migratory, or rather gregarious in its habits; and, 2ndly, because it feeds almost exclusively on green herbage, or the tender bark of shrubs, and is, therefore difficult to trap. The long-tailed field mouse is in no case compared with it, being very easily trapped with the same baits and traps as are set for house mice. The bank vole, distinguished from the field vole by being rather smaller, and being of a bright chestnut-colour on the back, may also be trapped; but a piece of Apple, or a Brazil-nut is more attractive to it than toasted cheese. The proportion of field voles, however, which can be caught by the most diligent trapping is nothing compared with what are left. I, too, live in West Cheshire, with a garden open on all sides to grass-land, and have a most unpleasant experience of these pests. They invade rockeries in winter, where they feed on the choicest evergreen alpine, such as *Ranunculus* and mountain Pinks, and are especially fond of the young growth and flowers of Hellebores. They make runs through the tufted Saxifrages, biting through the stems for the purpose. They generally live in warrens in some neglected breadth of grass, where everything should be done to dislodge them, putting paraffin and rough grit into the holes; but one's best friends when overrun with them are weasels. I encourage these in the garden in every way, and they become almost tame. They ferret the mice out of their holes, hunt them down by

scent, and finally make them change their quarters. I remember watching a weasel hunting a field-vole by scent when the ground was covered with snow. The mouse crossed a path close to me, running straight, and disappeared in a stone wall beyond. The weasel was then about a hundred yards behind, running in advancing rings of about ten yards diameter. There seemed to be no scent on the frozen snow, but the weasel ran from stalk to stalk of dry grass, projecting from the snow, putting his

Doubtless many of these are equal to the descriptions given of them, but not so here, and consequently I have had to stick to my old and trusted friend, Ne Plus Ultra, and if confined to one variety only it would be the above-named, as we have it in good bearing until destroyed by frost in November. William I. is our general early variety; some others are earlier, but not so prolific. With these two varieties a very long season of Peas of the best quality may be obtained. *W. O., Fota, Cork.*

ciety:—E. Ellis, Esq., Manor House, Wallington; J. E. Bonny, Esq., Marlborough, Swanley, Kent; G. A. Candler, Esq., Newlands, New Park Road, Clapham Park; James Gibson Dees, Esq., Flora Villa, Whitehaven; the Right Hon. Polydore De Keyser (Lord Mayor of London), Mansion House; Alfred Eastly, Esq., Upper Addiscombe Road, Croydon; Walter Furze, Esq., Roselands, Broom Road, Teddington; John P. C. Graves, Esq., Cane Cottage, I40, Upper Tulse Hill, and Mrs. John P. Graves; A. Hilden, Esq., Corkickle, Whitehaven; Frederick J. S. Horsman, Colchester; R. W. Ker, Basnet Street, Liverpool; W. P. Norbury, Esq., Brentford; Charles H. Page, Esq., Cardiff; John Peed, Esq., Mitcham Road, Streatham; John Raddenberry, Esq., Botanic Gardens, Geelong; Mrs. Courtenay F. Terry, Shrublands, Hersham, Walton-on-Thames; and John Woodbridge, Esq., Syon House, Brentford. The Chairman said that several of these had formerly been members of the Society, and were desirous of again joining them. The candidates were elected unanimously.

The Council.—The Rev. Mr. Wilks then rose and said it was well known to everybody that a certain amount of blame had been passed upon the Council for the action they had taken in resigning in a body, and then, as it were, with the same hand proposing the re-election of the greater number of themselves. It appeared to him that instead of any blame attaching to them for that action they should receive the most cordial thanks, for by their resignation they had enabled the Society if they liked to elect a new Council, or to infuse as much new blood into it as they chose; and by many of them offering themselves for re-election, they showed plainly that there was ample life in the Society to enable it to continue for many years to come. They had, in fact, utterly declined to act like the proverbial rats, deserting a sinking ship. He thought, therefore, that it would only be a graceful act if they refused to allow the Council to resign, but re-elected those members of the Council who were willing to continue their services. He therefore moved, "That this meeting begs to thank the Council for the opportunity which, by their proffered resignation, they had given to the Fellows of electing an entirely new Council, but respectfully declines to accept the resignation of the following members:—Sir Trevor Lawrence, Dr. Robert Hogg, Professor M. Foster, Mr. W. T. Dyer, Mr. Wm. Lee, Colonel Beddome, Mr. Sydney Courtauld, Mr. E. G. Loder, Baron Henry Schröder, and Mr. Geo. F. Wilson."

Mr. Harry Veitch, in seconding the motion (which was carried unanimously) said they had the utmost confidence in the names which had been proposed.

The Officers.—The Chairman announced that the election of the officers and Council would next be proceeded with. He remarked that with regard to the nomination of Baron Schröder for the post of Treasurer, the Council were very anxious that the Baron should act in that capacity, and did their best to induce him to accept the post. Baron Schröder, however, was unfortunately obliged, out of paramount considerations of health and work, to decline, and he might inform them that he had received a letter from the Baron in which he expressed his extreme regret at being unable to attend the meeting that day, inasmuch as he was confined to his bed with an attack of bronchitis. He also regretted to say that Professor Foster was prevented from being present in consequence of indisposition. Colonel Beddome, who was one of the nominees for the post of Treasurer, and who would have made an excellent officer, had also declined to serve, and the Council had unanimously nominated Mr. Morris for the position. A good many of the Fellows did not know, perhaps, who Mr. Morris was. For their information, he might state that Mr. Morris, after a distinguished course at the University, had been engaged in horticultural matters in the colonies for many years, and had occupied many important positions in connection with them. He (Sir Trevor) was informed that the gardens at Jamaica, under Mr. Morris' control, had always been well managed, not only from a horticultural but also from a business point of view, and the Council would be fortunate if they succeeded in obtaining the services of that gentleman.

Mr. Wynne and Major Lendy then formally withdrew their opposition respectively to the nomination of Mr. Dyer and Mr. Morris as members of Council.

The Last Special Meeting.—The Secretary, acting on an intimation from the chair, then read the minutes of the special meeting held on January 10, and the same were ratified.

FIG. 36.—BIOTA SIEBOLDI. (SEE P. 205.)

nose against them, and evidently guided by the scent which they caught and retained. He finally disappeared in the wall in the same spot as the mouse. *C. W. Dod, Edge Hall*

GARDEN PEAS.—Had it not been for the following remarks of the Editor I should hardly have troubled your readers (p. 151):—"Peas, like other plants, vary with locality, so that what will suit one place will not grow satisfactorily in another." This has been my experience, and especially with Peas. For many years I have bought and tried most of the giant-podded and other new Peas that have been offered, and in most cases to be disappointed.

SOCIETIES.

ROYAL HORTICULTURAL.

Annual Meeting.—The annual meeting of the members of this Society took place in the East Crush-room of the Royal Albert Hall, on Tuesday afternoon, February 14. Sir Trevor Lawrence, Bart., M.P., presided, and there was a large attendance of Fellows. The Secretary read the notice convening the meeting, and the minutes of the last annual general meeting, which were duly signed.

New Members.—The Chairman read the following list of candidates for election as Fellows of the So-

The Report of the Council.—The report of the Council of the Royal Horticultural Society for 1887 with the financial statement, was taken as read, having been previously freely distributed among the Fellows.

The President's Statement.—The Chairman, who was heartily cheered, next rose to move the adoption of the report. He said it now became his duty to make a few remarks with regard to the present position of the Society, and he must say that the Society occupied a more hopeful position now than it did a year ago. That arose mainly in his opinion from the fact that they were now no longer trammelled by a connection with South Kensington. In saying that he had no desire to recall disagreeable memories, but he might here say, with reference to the gentlemen who thought it their duty to send in their resignations as members of the Council—Colonel R. Trevor Clarke, Major F. Mason, and Mr. W. Haughton—that he thought the thanks of the Council and of the Society were due to them for the services they had rendered during many years. They did not altogether agree as to what was wisest to do for the future of the Society, but these gentlemen loyally accepted the position when they found they were in a minority, and, with a view to rendering the future consultations of the Council more satisfactory, they withdrew when they found that the views they had put forward no longer commanded the general acceptance of the Council. Colonel Trevor Clarke was very well known in the botanical and horticultural world, and apart from other considerations, his resignation in this respect was a loss to the Society. The absence of the other two gentlemen would also be felt; and he might especially say with regard to Mr. Haughton, that the Society would have liked to have ensured the continuance of his services if possible. He (Sir Trevor) had not the least doubt, now that the vast majority of the Council were at all events of one opinion, that the majority were agreed that the connection of the Society with South Kensington had been prejudicial to the interests of the Society. There had, amidst the gloom, been transient gleams of sunshine, but he was sorry to say that they had not taken advantage of those transient gleams of sunshine in a financial sense to put money by for a rainy day. On the contrary these glimpses of sunshine had done rather more harm than good, as they had had the effect of leading the Society into rather extravagant courses. If it had not been for the death of the Prince Consort, the circumstances of the Society probably would have been totally different. They would have had the enormous advantage to be derived from his prudent and wise advice and great influence; and had he lived, the story of their connection with South Kensington would doubtless have been a far different one. As they knew, about this time last year negotiations were going on with the Albert Hall Corporation. Those negotiations never came to anything, and he was never sanguine that they would do so. He must confess that he never believed it was likely that their negotiations with the Royal Commissioners of the 1881 Exhibition would lead to a result satisfactory to the Society. Reference was made in the report at the previous annual general meeting to the desirability of getting a site for the Society on property of the Royal Commissioners. A site was offered to them by the Royal Commissioners, not in a good position, it was true, though if it had been adequate in size, it might perhaps have been adopted by the Society. But the offer was encumbered with this perfectly impossible condition—that it was not to confer on the Society any right, either moral or legal, to the use of the gardens and conservatory. They would thus have found themselves hampered with the incubus of a building of considerable costliness; and the use of which would have been annihilated if they had not had at the same time the use of the gardens and the conservatory. Then there was an offer to let the gardens to them at a rental of £1000 a year. That in the present financial position of the Society was impossible. To have paid the rates and taxes as well as to have incurred the cost of the maintenance of the gardens would have been an enormous additional burden, and whatever the financial position of the Society might be now, it would have been infinitely worse if they had entered into any such agreement as that suggested by the Royal Commissioners. Thus it was that the negotiations that had been going on year after year and the offers made by the Royal Commissioners had fallen on somewhat stony ground, and it had long been obvious that the cessation of the connection with South Kensington was only a matter of time. The time had now arrived for a complete and definite

severance. In thus going away they would leave a great deal behind them. He was sorry to say that the Society had spent on the grounds in which they were now located £78,557 18s. 4d., or, in round figures, £80,000, and on leaving they would receive not one halfpenny of consideration. Whether or not the Society was acting wisely in bringing its connection with South Kensington and the Royal Commissioners to an end, there remained this fact, that it left this enormous sum of money behind, and he was afraid he might also say it left behind also some small portion of its credit and renown. It was now their business to look the state of affairs in the face, and see if they could not, by settling the Society on a new basis, and finding it a proper home, re-establish its character and position. They had received very great assistance from horticulturists in all parts of the country, and he believed that when the proposals that to-day would be laid before the Society became known that assistance would be largely increased. The circular issued to the Fellows on December 9 stated the proposals of the Society, among these being the maintenance of Chiswick gardens, the conduct of fruit and vegetable trials, and the establishment there of a school of gardening. It was a remarkable circumstance that this country, which was the greatest gardening country in the world, was the only country which had not got a school of gardening [while Germany has no fewer than thirty-three]. As to the Charter, they had consulted their solicitors, who advised them that once possessed of a Charter it was exceedingly difficult for a society to get rid of it, and a costly and troublesome proceeding to get it amended, and that consequently if possible it was desirable to go on with the present Charter. No doubt a great deal of the Charter was absolutely obsolete, and when they departed from South Kensington would refer to a state of things that had entirely ceased to exist. But he thought, in face of the advice they had received, they had better rub on with the present Charter as long as possible. With regard to the bye-laws, a considerable portion of them was also obsolete.

With reference to the Council, he should like to mention that they had placed their resignations in the hands of the Fellows with the view of leaving the Society at perfect liberty to make whatever selection they thought proper of a new Council. It had been suggested in one quarter that as they had proceeded to re-nominate a certain number of their body, their resignations were scarcely sincere; but a little reflection and study of the bye-laws would show that this was not so. There was not one of them who would not most willingly resign his place to make way for anybody else if it could be shown to be of the slightest advantage to the Society. He would like to refer to some comments that had been made on the fact that they had on the Council two gentlemen connected with the national establishment at Kew. It was feared that the rest of the Council would not be able to hold their own against them. Now if thirteen members of the Council were unable to hold their own against two, whether they came from Kew or anywhere else, they were unfit for their position. But the fact was that they had acted in the most perfect harmony with them, and the fact of the Council having amongst them the head of the greatest botanical and horticultural establishment in the world was of the greatest advantage.

With regard to the outside Committee, the Council had met with the greatest possible assistance from them. Out of the seven gentlemen proposed on the Committee for election to the Council, the Council had adopted four. Two of the gentlemen whose resignation the Fellows had declined to accept would find it necessary, they said, to retire, and would make way for two others of the seven proposed by the outside Committee. The result would be that out of the fifteen members of the new Council, eight would be old members and seven would be new. Downstairs in the Conservatory they had convincing evidence that persons interested in horticulture had no intention of deserting the Society. He did not believe they would. His experience was that the Royal Horticultural Society maintained its great reputation as a horticultural society as high as ever it did. It had unfortunately been in difficulties in regard to financial matters, and the real difficulty now was the financial difficulty. It would be absolutely necessary that the Council should be provided with sufficient funds to carry on the work of the Society, as they should not incur liabilities if they saw no prospect of being able to deal with them. But when matters were placed on a new footing, he

believed that the amount of support required, which was not very large, would be forthcoming. He was very glad that there were now no serious matters in dispute existing. The Council were entirely unanimous as to the policy which was to be pursued and were in entire unanimity with the out-side Committee.

Mr. G. Deal then read the—

REPORT OF THE SPECIAL COMMITTEE OF THE FELLOWS PRESENTED TO THE ANNUAL MEETING ON FEBRUARY 14, 1888.

The committee appointed in pursuance of a resolution passed at a special general meeting held on December 13, 1887, and confirmed at the subsequent meeting on January 10, 1888, deems it expedient, on the occasion of the annual meeting (albeit the committee has been only a short time in existence), to lay before you a report of its work and deliberations up to the present time.

The members originally nominated were Sir Trevor Lawrence, Bart., M.P., the President of the Society, Baron Schröder, Professor Michael Foster, and G. F. Wilson; members of Council, Messrs. A. H. Smee, H. J. Pearson, H. J. Veitch, Shirley Hibberd, George Paul, and Dr. Masters.

At the first meeting of the Committee, in accordance with the powers conferred upon it, Dr. Masters was elected Chairman, and there were added to our number the following gentlemen—Messrs. J. Woodbridge, J. Douglas, R. Ker, T. B. Haywood, H. Turner, Rev. W. Wilks, and G. Deal, the last-named gentleman being afterwards requested to act as Secretary. Messrs. Herbst and Marshall were at a subsequent meeting added to the Committee. Some gentlemen whom the committee would most gladly have added to its number were, for various reasons, unable to respond to the invitation sent to them. The selection of the members of the committee has been made with a view to secure as complete a representation of all sections and interests of the horticultural community, including representatives of the special societies, as circumstances permit.

NOMINATIONS TO COUNCIL.

The next step taken was to suggest to the Council the names of Messrs. A. H. Smee, H. J. Veitch, George Paul, T. B. Haywood, C. R. Serase Dickens, J. Woodbridge, and Rev. W. Wilks, to fill certain of the anticipated vacancies in the Council at the annual meeting. The Council at once adopted some of these names, and it is believed that arrangements may be made at the annual meeting whereby some others may be selected in conformity with the recommendations of the committee. Your committee regrets exceedingly that Baron Schröder, whom it had suggested to fill the position of Treasurer, finds himself unable to undertake the duties of the office.

EXTRAORDINARY VACANCIES IN THE COUNCIL.

The Committee begs to recommend that as two extraordinary vacancies in the Council are anticipated after the election this day, such vacancies should be filled by the election of Messrs. T. B. Haywood and J. Woodbridge.

NEW PREMISES FOR THE SOCIETY.

After careful consideration of the requirements of the Society, and after an inspection of numerous premises by means of a sub-committee, your committee submits that the undermentioned premises seem to meet the present requirements of the case better than any other, and therefore strongly recommend that they should be forthwith secured.

Offices.—The committee is of opinion that the first floor of No. 111, Victoria Street, is well suited for the London headquarters and Offices of the Society, and for the housing of the Lindley Library, in case the trustees consent to its being placed there.*

The premises occupy a good position, almost midway between the Victoria Station and St. James' Park Station on the District (Underground) Railway, and within a few minutes' walk of either. The ground-floor of the house is occupied by the "Metropolitan Drinking Fountain Association," and the upper floors are let out in sets of chambers. The first floor consists of two rooms and the usual conveniences. The smaller of the rooms is 16 feet 2 inches long by 8 feet 6 inches wide, and could be used as a clerk's room. The larger of the rooms is a spacious and convenient apartment, 42 feet 6 inches long by 22 feet 9 inches wide. It has a coved ceiling and is very lofty, being 18 feet high, so that it is well adapted for the purposes of library, reading, and Council room, and for business purposes generally.

A plan of the premises and a sketch of the larger room have been prepared, which will explain the extent of the accommodation much better than mere words can do. These premises are offered at a rental of £120 per annum, free from rates and taxes.

Arrangements for Shows and Meetings.—Your committee having in view, at this particular time, only the Metropolitan requirements of the Society, further submits that the Drill Hall of the London Scottish Rifle Volunteers is well suited for holding large exhibitions, smaller meetings, and for the assembling of the several committees. It is situated in James Street, Victoria Street, within two minutes' walk of St. James' Park Station on the District (Underground) Railway. It is close to the Army and Navy Stores, and within two or three minutes' walk of No. 111, Victoria Street, the premises already recommended for the offices of the Society. The hall is 135 feet long by 72 feet wide, is lofty, has a fairly good light, and is generally suitable for the purposes indicated. It has a back entrance which can be made use of for carrying in and removing exhibits, and a good carriage entrance adapted for the arrival and departure of visitors. There is room available in the basement for the storage of the necessary tables and tressels. Your committee has instituted inquiries and opened negotiations with the Committee of the London Scottish Rifle Volunteers, and now begs to recommend that the Society should confirm the offer made by the committee to pay a rental of £100 per annum, from March 25 next, in order to secure the use of the hall for twenty meetings during the year; the rent to include the cost of storage room in the basement for the Society's tables and tressels, and, if possible, to secure the use, on show days, of the luncheon-room and probably of the committee-room for a few hours in the morning occasionally.

* The trustees of the library are not absolutely bound by their deed to place the library on the Society's premises, after its removal from South Kensington, though there is little doubt that they would do so. M. T. M.

Propositions to hold exhibitions, &c., at Chiswick and in other localities in London and in the provinces, will form the subjects of future deliberation.

NEW BYE-LAWS AND GENERAL POLICY.

The committee has under consideration the construction of new bye-laws intended to facilitate the carrying out of as complete a horticultural policy as possible—one in which all aspects and departments shall be considered, to the undue preponderance of none, but to the general advantage of all. A more adequate representation of horticultural representatives and of diverse interests in the Council is aimed at, as well as the creation of an enlarged constituency, especially in the provinces, by means of reduced rates of subscription, adequate privileges and representation on the governing body being secured to the subscribers of whatever grade.

It is hoped that by the institution of such a policy the Society may become the central Horticultural Society of the Empire, with branches and representatives in every district of the country, and with committees and sub-committees to meet the wants of specialists and those interested in particular departments.

SECRETARY AND MANAGER.

The committee urges the paramount importance of appointing a well-qualified paid Secretary at as early a date as possible, the services of such an officer being, in its opinion, indispensable for the adequate discharge of the work involved in the reorganisation of the Society.

Lastly, as these and other schemes for the future development of the Society must of necessity occupy some considerable time before they can be put into working order, your committee suggests that it should this day be reappointed with full powers, and that it should continue to operate, in the same satisfactory spirit as heretofore, with the Council in all matters relating to the welfare of the Society.

Signed on behalf of the committee,

MAXWELL T. MASTERS, Chairman.

GEORGE DEAL, Secretary.

February 14, 1888.

Dr. Masters, the Chairman of the Committee which presented the above report, expressed satisfaction at the harmony and co-operation which had existed between it and the Council. It might have been thought that there would have been a little jealousy between the two bodies, but there had been none. The new policy which was indicated was substantially the same as that initiated in the Council by Professor Foster and Mr. Dyer, and already approved at two successive meetings by the Fellows. Having dwelt upon the necessity of attending to the requirements of the Society outside the metropolis he referred to the fact that the Lord Mayor of London, that day elected a Fellow, being a Belgian, must of necessity be a horticulturist. He believed it would fall in with the Lord Mayor's views if they were to organise some meeting, say a Rose meeting, at the Mansion House, or some other part of the City, on the occasion of the visit of some Belgian friends to the Lord Mayor. Dr. Masters threw this out merely as a suggestion, not being in any way authorised to make any such statement definitely. As to the policy of the Society, one great fault of their Society hitherto had been that they had looked upon horticulture as a plaything of the rich, or as a mere money-grubbing machine for the few pecuniarily interested in horticulture. But horticulture had far higher aims than this. It had involved in it the interests of the country at large. The agriculture of the future would be to a large extent horticulture, and the Society had got to teach agriculturists how to earn a living. It seemed to him that the Society had not sufficiently considered the interests of the practical gardeners of the kingdom, many of whom perhaps could not afford to pay the subscription, and whom it might be well to admit at a lower subscription, and so endeavour to promote their education and welfare, and raise them in the social scale. It might be said this was a very large scheme but they did not expect to carry it out all at once. He believed in evolution and in that gradual slow growth according to circumstances, which would ultimately land them where they hoped to be, while revolution would only land them in confusion and anarchy. Personally, he did not think they would get on long without a new charter, but much might in the meantime be done by altering the bye-laws. These bye-laws should secure a reduced rate of subscription, and should facilitate the formation of branches in every county of the kingdom, with local secretaries and other representatives who should have a voice in the general council of the Society. Hitherto the Society had taken a very inadequate and one-sided view of its duties and responsibilities. It had had a splendid army, but one ill-organised and ill-led. The occasion was now offered for raising the Society to the level of its opportunities and national responsibilities. If the Fellows thought so some one of their number should propose the re-election of the Committee—if not the members of the Committee should be dismissed to those duties from which they could ill be spared, and which were so much more congenial to them than constitution mongering.

Mr. Cannell asked whether they were free from the obligation of the £80,000?

The President: We shall be free from this money—if that is what you mean. I am afraid there is no chance of getting it back. It has now fallen into the hands of the Royal Commissioners of the 1851 Exhibition.

The reports of the Council and of the Outside Committee were then adopted.

Re-election of the Outside Committee.—Mr. Roupell moved, and Mr. Wynne seconded: "That the Outside Committee be requested to continue to act."

Mr. Cheale, in supporting the motion, said he hoped the Committee would continue to do the good work which it had performed during the past month. The resolution was carried unanimously.

Some scrutineers having been previously appointed, and a ballot taken, it was reported that the old members of the Council already named by the Rev. Mr. Wilks, and also Mr. D. Morris, Mr. A. H. Smee, Mr. George Paul, Mr. Harry Veitch, and the Rev. W. Wilks himself had been elected by forty-four votes against six.

The Chairman asked that the recommendations of the Outside Committee as to the acquisition of the new premises and drill-hall on the terms mentioned should be sanctioned, in order to strengthen the hands of the committee. A motion to this effect was accordingly passed.

On the motion of Mr. Veitch, seconded by Mr. Pearson, a vote of thanks was accorded to Mr. Laing, builder, for assistance rendered by him to the committee in finding and securing these premises.

A hearty vote of thanks was then passed to Mr. Haughton, Captain Bax, Major Mason, and Colonel Trevor Clarke; Dr. Masters taking the opportunity of calling attention to the prolonged services and great horticultural attainments of Colonel Clarke.

Colonel Trevor Clarke in acknowledging the vote of thanks in which he had been included, said he had joined the Society when he was young; he had grown old amongst them; he loved and honoured the Society, and he hoped to die in its service.

A New Bye-law.—The President said he wished to propose the following bye-law, the absence of which had been found a source of great inconvenience:—"The President may call a special general meeting of the Society if he consider it necessary, any bye-law to the contrary notwithstanding, subject to not less than a week's notice being given." Formerly it was necessary to receive the sanction of the Council before a special meeting could be called, and the proposed bye-law would prove a matter of great convenience. The bye-law was adopted unanimously.

A vote of thanks to the President concluded the proceedings.

THE FORTNIGHTLY MEETING.

The conservatory was made attractive by the display of flowers in season. Cinerarias, Narcissi, Primulas, house Rhododendrons, alpine plants, and an interesting miscellaneous collection, chiefly Orchids, from the gardens of the President, Baron Schroder, Mr. Smee, Messrs. James Veitch & Sons, F. Sander & Co., and others. The Royal Gardens, Kew, furnished a few plants in flower, inclusive of the gorgeous *Brownea grandiceps*. Fruit was shown in large quantities by several growers of note, that of Messrs. Rivers consisting of, many dishes of Apples, together with some capital examples of Oranges, Lemons, and Citrons; while Mr. C. Ross and Mr. Ford showed Apples.

Floral Committee.

Present: G. F. Wilson, Esq., F.R.S., in the chair; and Messrs. W. Goldring, J. Laing, H. Bennett, J. Fraser, H. Herbst, W. Bates, Dr. Lowe, G. Paul, G. Duffield, C. T. Drury, R. Dean, W. Holmes, B. Wynne, C. Pilcher, J. Dornay, H. M. Pollett, J. O'Brien, E. Hill, A. J. Lendy, T. Baines, and J. Walker.

Orchids.—These flowers and plants were shown in considerable numbers by Baron Schroder (gr., Mr. H. Ballantine), The Dell, Egham. Of these *Odontoglossum crispum* Stevens was remarked for the great size of the spike shown—the flower, prettily fringed, has white petals spotted with brown, and sepals creamy-white with bars of a brown colour. *O. c. xanthotes* is a very beautiful pure white form, with a yellow blotch extending the whole length of the lips. Several cut spikes of the fine varieties of *Lælia anceps* grown at The Dell were likewise shown. Mr. H. M. Pollett, Fernside, Bickley, exhibited the fine *Dendrobium nobile* Cooksoni, its petals are white with a deep purple base, the reverse of the whole limb being a light shade of that colour; the sepals are white, suffused with pink, the lip is also white with purple blotch.

The collection from Sir Trevor Lawrence's garden was of great variety and number, and was strong in *Dendrobium*. *D. chrysoideum*, a flower mostly of a white colour, with petals and sepals tipped with rose, and with yellow and brown bars on the throat, was deemed worthy of a Certificate. The flower has a width when fully open of 2½ inches, and is showy; a pretty light form of *D. nobile*, named *intermedium*, is striking, owing to the great contrast of the lip in colour to that of the other parts of the flower; *D. n. Cooksoni*, a fine form, but less so than the plant of Mr. Pollett's, which obtained a Certificate; another *Dendrobium* was *D. amethystoglossa*. *Cattleya Percivalliana*, a plant with eight blooms, was a welcome piece of bright colour; *Odontoglossum crispum punctatissimum* is a showy white form, with rosy-purple suffusion, and darker minute spotting. *O. crispum pardalinum* was shown in a very fine piece, also *O. nebulosum pardalinum*; it is of dwarf habit, the flowers white, with dull brown spots on the lower half of the segments closely packed together; the white *O. Oerstedii* major, *Lælia anceps vestalis*, and *L. harpophylla*, two beautifully contrasting species, were observed, as likewise *Masdevallia Gargantua*, a singularly marked and formed species—interiorly it is purple-brown, the upper portion, margins, and the three tails are greenish-yellow, and being poised with the mouth of the flower turned uppermost, the singular colouring is easily observed. Another plant of much rarity was *Evelyna kermesiana*, bearing a short spike of small purple flowers.

A number of Orchids came from the gardens of A. H. Smee, Esq., The Grange, Wallington (gr., Mr. G. W. Cummins), consisting chiefly of species that are rare, of recent introduction, and possessing small flowers. These were *Oncidium Russelianum*, a small brown flower, with a white and yellow lip; a species of *Maxillaria*, yellow in form, near *M. picta*; *Angraecum hyaloides*, with small white flowers, the habit of plant very dwarf; *Dendrobium Kingianum* album, *Odontoglossum* (Erstedii) and *O. O. major*; the minute and curious *Masdevallia culx*; *Vanda cristata stricta*, with creamy white flowers with green tips and purple stripes. *Sophranitis violacea* is a little gem in rosy-purple, and habit exceedingly dwarf. *Ophrys lutea* was shown in flower, the tall spike carrying three blooms like yellow discs, with a purple patch in the centre of each.

A number of *Dendrobiums*, consisting of several forms, were shown of *D. euosmum*, *D. splendidissimum*, *D. endocharis*, &c., came from Messrs. Veitch & Son's nursery, Chelsea. *D. euosmum* and *D. e. leucopterum* were obtained by crossing *D. endocharis* and *D. nobile*. In the second-named hybrid we have a purer white flower than that of the first-named, but the blotch of purple on the lip is smaller. The other hybrid *Dendrobium* is *splendidissimum*, *D. aureum* × *D. nobile*. Three plants of different forms of *Odontoglossum triumphans* were shown; one is bright yellow, with a few widely-separated light brown spots; lip and throat white, tipped with brown. Another is very dark brown and tipped with yellow, the lip yellow as to the base and brown along all the margins. The third seemed to be in all points intermediate between these, and the brown and yellow shades paler.

A few plants of great merit came from the nursery of Messrs. Sander & Co., St. Albans, the finest being a plant of *Lycaste Skinneri* Imperator, a magnificent form, large, with petals of brilliant crimson; sepals rose-red, vanishing into white at the points; and lip of crimson, mottled with white. *L. S. alba* was exhibited in two examples. This is still one of the best, and by no means common. *Odontoglossum maculatum* anceps, has flowers with brown sepals and yellow petals, spotted at the base with brown the lip yellow crimson spotted.

Mr. Wright, gr. to C. N. Major, Esq., Cromwell lentiginosa, a brilliant golden-yellow flower set on a house, Croydon, showed a specimen of *Dendrobium Hilli*.

From Kew we noted *Bletia verucunda*, *Cecelogyne* a short erect stalk. The lip, the most conspicuous feature, is 2 inches wide, and is edged and spotted with brown.

The little *Holothrix secunda* mentioned in our issue for Feb. 4; *Corydalis Ledebouriana*, and a flower of the magnificent *Brownea grandiceps*, noticed on another page, completed the list of Kew plants.

An interesting exhibit, made to show the origin of the warm house Rhododendrons was made by Messrs. J. H. Veitch & Sons, to which we must allude next week.

The new *Ardisia mamillata*, figured in our pages recently, was shown in berry. It looked likely to prove a "gardener's plant," and is quite as decorative as the old *A. crenulata*.

A pretty group of Alpines and other plants came from Messrs. Paul & Son's Old Nursery, Cheshunt. There were *Saxifragas*, *Prionas*, *Helleborus*, *Cyclamen Coum*, *Megasea Stracheyi*, *Rosa viridiflora* in leaf and bud; flowering bulbs of *Iris Histrion* from the Lebanon, and *I. reticulata Krelagei*. A handsome *Lilac* named *Ilyacinthiflora* was observed, it is a compact purple variety, and apparently a good flowerer.

Mr. C. Turner, Royal Nurseries, Slough, showed two new winter flowering *Carnations*, excellent for cutting purposes, one is a red edged *Picotee*-like flower, with white ground; the other a crimson and slaty flake.

Messrs. Barr & Son, King Street, Covent Garden-W. C., sent a collection of bulbous plants, both in pots and out. *Crocus chrysanthus splendens*, is a very noticeable *Crocus*, the orange-red of the stigmata shining out with great brilliancy against the butter yellow of the perianth segments. *Narcissus minor* was largely shown. There were also the *Tenby Daffodil*, *Narcissus Poeticus ornatus*, the *White Hoop Petticoat Narcisse*, &c. with *Crocus Imperatii Galanthus Elenesii* (a fine form of *Snowdrop*), and *Chionodoxa Lucilie*, *Bronze Banksian Medal*.

A group of *Narcissi* came from Mr. T. S. Ware, Hale Farm, Tottenham, for which a *Silver Banksian Medal* was awarded. These were set up in a novel way with wire, so that the bunches formed a kind of diamond fan. *Chionodoxa Sardensis*, *Scilla Sibirica* and other flowers were interspersed.

Beautiful *Cinerarias* of refined yet bright colours, were contributed by Mr. J. James, Woodside, Slough. A collection of Chinese *Primulas* came from the same grower. A *Silver Banksian Medal* was awarded.

Messrs. H. Cammell & Sons, Swanley, showed many plants of their fine strains of *Primula sinensis*, viz., *White Perfection*, *Swanley Giant*, *Crimson Perfection*, and others. The smallness of the pots in which the plants were growing was noted by most persons. A few fine *Cinerarias* came from the same growers.

From that treasury of rare things, *Pendell Court*, Mr. F. Ross, gr. to Sir G. Macleay, exhibited *Dombeya Wallichii*, having a corymb of rosy-red flowers possessing yellow anthers. The diameter of the head was about four inches, so that it fell far short of that of the *Brownia grandiceps*, which it somewhat resembles at a distance. The other flowers from these gardens were *Acacia verticillata*, a free blooming variety, with yellow flowers and spiny shoots, and *Franciscea calycina*.

From the Society's Gardens at Chiswick there came four baskets of seedling *Helleborus* in flower, the colours of the sepals being in all cases dark.

Fruit Committee.

Present: T. F. Rivers, Esq., in the chair; and Messrs. W. Paul, J. Wright, H. Wier, J. Smith, J. Burnett, T. J. Saltmarsh, S. Ford, J. Woodbridge, Chas. Ross, J. Roberts, J. Cheal, Ch. Howe, G. W. Cummins, Wm. Denning, W. Marshall, H. J. Veitch, J. Lee, P. Crowley, and J. Willard.

We must defer our report of this meeting till next week.

Obituary.

JOHN SMITH.—We have to record the death on the 14th inst. of John Smith, the veteran ex-curator of the Royal Gardens, Kew. John Smith was born so long ago as October 5, 1798, at Aberdour, in Fifeshire. What we said of him in 1876 when we published an autobiographical notice and a portrait remains true.

His extraordinary knowledge of plants and of every circumstance connected with the history of the Royal Gardens, no less than his contributions to Botanical Science, have given him a claim to the respect of horticulturists which none will wish to gainsay, while the sympathies of all will be specially felt for one to whom the loss of sight is a more than usually sad deprivation.

In the autobiographical notice above referred to Mr. Smith narrates how he received his early education in the parish school of Pittenweem; he early commenced the cultivation of Scottish wild plants, his botanical knowledge being fostered by the aid of Lee's *Introduction to Botany*. In 1815 he worked as

a journeyman at Raith, near Kircaldy, doing the drudgery common in Scotch gardens in those days, and living in a miserable back-shed bothy. In 1816 he entered the gardens of the Earl of Moray at Donniebrielle, from whence, in the following year, he walked in the course of three days to Caley House, Kircudbrightshire; here he increased his botanical knowledge, and in the following year proceeded to the Royal Botanic Garden, Edinburgh, where the collections of plants were considerable. Here he met with congenial spirits, and although he and three others lived in a back shed one-roomed bothy, his wages being only 9s. per week, personal discomforts were forgotten, and botanical studies were eagerly pursued. He managed to purchase books and specimens, and to gain a considerable knowledge of plants, as well as of land surveying. In 1820 he came to London, and was appointed to fill a vacancy in the Royal forcing gardens at Kensington. In 1822 he entered the Royal Gardens, Kew, then consisting of only 9 acres; the hothouses then were, with one exception, all lean's-too, and heated by small flues, having in all thirty-one furnaces, attended to by the young gardeners in rotation, and who had to perform the drudgery work in clearing away the ashes. His wages at that time were 12s. per week, out of which he still managed to buy books. As an illustration of the eagerness felt by some young gardeners at that time we may mention that Smith had observed in a book shop a second-hand copy of the *Epitome Horti Kewensis*, but the price being more than he could afford, he waited for several weeks till he had acquired the sum required when he started off to purchase the book, which he had just done, when one of his comrades entered the shop on the same errand.

From this time forward he advanced gradually under Mr. Aiton, but the condition of the gardens was such that great dissatisfaction was expressed at their management, and on February 12, 1840, the then Secretary of the Royal Horticultural Society (the late Mr. Bentham), and Dr. Lindley (assistant Secretary), received a note from the Secretary to the Treasury, offering the whole of the Kew collections upon certain conditions to the Horticultural Society. The Society unanimously declined to accept the offer, feeling that it would be a disgrace to the nation to break up the Kew collections.

The late Mr. Heward also protested against the change, the consequence of which was that the garden was transferred on April 1, 1840 to the Commissioners of Her Majesty's Woods and Forests, and on March 31, 1841, on the resignation of Mr. Aiton, Sir William Hooker became director, and with him, as we know, commenced a new era in the history of the garden.

Smith powerfully aided Sir William Hooker in his plans for the reform and improvement of the garden.

During all this time Smith continued his botanical studies and achieved a great reputation for his knowledge of Ferns.

In 1861 his sight failed, so that in 1864 he retired from his post, after 44 years' service in the gardens, carrying with him the respect of all who knew the vast extent of his services to Botany and Horticulture. Blindness, however, by no means put a stop to his labours, book after book followed from his pen, and his vast knowledge of plants and his intimate acquaintance with all the details of the history of the Royal Gardens, Kew, and on horticultural matters generally, furnished materials not only for books, but also for numerous letters and communications to the horticultural press; while, as a referee, his great stores of knowledge were always at the disposal of those who sought them.

DIED.—On the 10th inst. at Broomhill Gardens, Tunbridge Wells, Mr. JAMES NEVE, in his thirty-ninth year. Mr. NEVE had been head gardener to Sir D. Salomons, Bart., for the last ten years.

NOTICE.—Owing to want of space much matter is unavoidably postponed to our next issue.

NOTICES TO CORRESPONDENTS.

Correspondents sending plants or fruits to be named, or asking questions demanding time and research for their solution, must not expect to obtain an answer to their enquiries in the current week.

ADDRESS.—Will G. B., who wrote about Peas, kindly send his name and address, not necessarily for publication?

APPLES: *A. C. G.* Owing to the time of year the distinctive marks of the several fruits sent for names have disappeared, and we cannot undertake to name them. Send earlier next autumn.

BOOK, GARDEN ARCHITECTURE: *Lady Amateur*. It is in the German language, and so far as we know there is no translation.

BULBS: *G. May*. Your *Lilium* bulbs are badly infected with the bulb-mite to which we have so often referred. Destroy your stock of infected bulbs.

LEMON-SCENTED VERDENA: *T. H.* These strike best from half-ripened young growth put in during the spring, and afforded a bottom heat of 80°. Autumn is not the best time; and your attempt lately to strike the cuttings was due to want of the proper degree of warmth, and probably to the state of the wood chosen.

MARQUERITE (CHRYSANTHEMUM) SEEDS: *T. H.* Any of the species will germinate in about 3 weeks—in less time, if afforded warmth in a hot bed, but from which they must be removed in 3 or 4 days after germination.

MARQUERITE CUTTINGS DYING: *T. H.* Without any data how can we assist you? Send some of them, and the soil they were put into, with full particulars of treatment given.

NAMES OF PLANTS: *G. P.* *Juniperus drupacea.*—*H. E. F.* *Lælia albid.*—*J. B.* *Odontoglossum Rossi majus* var. *pallens.*—*L'Allegro.* *Rivinia humilis.*—*W. J. A.* It is a very pretty variety of *Dendrobium nobile*, but it has no varietal name. Recent importations show that this species varies considerably.—*A. Parrott*, 1, *Epidendrum atropurpureum* (*E. macrochilum*); 2, *Oncidium Cavendishianum.*—*W. A. I.* *Lycaste cruenta*; 2, *Lavendula Stoechas*; 3, *Acacia armata.*—*A. Moulton*, 1, *Hedera elegantissima marginata rubra*; 2, *H. e. m. major*; 3 and 5, *H. sub-marginata*; 4, 6, and 7, *H. e. m. grandis*; *T. H.* *Dendrobium speciosum.*

ODONTOGLOSSUM VEXILLARIUM: *Young Inquirer*. It is impossible to say for certain why your bulbs make a second growth, but we imagine it must be from some check during growth, as a consequence of which the proper development was not made.

ORCHID CULTURE: *J. W.* *The Orchid Manual*, by B. S. Williams, Victoria Nurseries, Upper Holloway, N.

PAINTING OF AFRICULA: *T. E. H.* It is scarcely suitable for our columns, so that we must decline it with thanks.

ROGERIA GRATISSIMA: *Peto*. Does best in a warm greenhouse.

SIX CONSERVATORY CLIMBERS TO BE ORNAMENTAL FROM JANUARY TO MAY: *J. H. C.* *Tecoma Jasminoides*, *Senecio macroglossus*, *Lapageria rosea* and *alba*, *Acacia Richeana* and *pulchella*, *Polygala Dalmaisiana*, *Habrothamnus Newellii*.

VINE: *W. A.* By blight you probably mean the Vine mildew. This is often found to attack the Vine out of doors in this country, and it is one of the chief reasons the Grape Vine is not more grown for its fruits. The fungus had doubtless passed from the outdoors Vine to the other part of the Vine in the greenhouse. There is nothing for it but to treat the Vine as a warm-house plant.

VINE LEAVES: *J. M.* The appearance is probably caused by the paint. There are no traces of either fungus or insect.

Lily Gardens, Twickenham, Middlesex, for the first time offer to the Public this beautiful variety, superior both in its blooms and foliage to any other yet offered. The stock is limited. All Orders will be sent in rotation, with an engraving and instructions for planting, &c. Price 25s. per square yard, packing included. Cash with Order.—Apply as above.

By Royal Letters Patent.—Carbon Cones.

LETHORION (VAPOUR CONE).

For the distribution of certain principles in a state of vapour, in Greenhouses and Conservatories, whereby their active properties are most closely brought into direct and intimate contact with vegetable productions, for the purpose of DESTROYING PARASITIC LIFE with a certainty hitherto unachieved, and without hurt or prejudice to the most delicate and fragile organization of plant life. The old system of fumigating with cloth or paper is now quite unnecessary.

Cone.	cu. feet.	PRICES.	Per case.
No. 0.	50 (for Window Cases and Small Frames from 10 cubic feet)	Each 6d.	Two doz. 10s. 6d.
" 1.	100 (for Frames, &c.)	9d.	15s.
" 2.	500 (for Small "Lean-to's," &c.)	1s. 3d.	One doz. 13s. 6d.
" 3.	1000 (for general use in Larger Greenhouses)	2s.	Half doz. 11s.

Directions for use with each Cone.

THOMAS GREEN & SON, LIMITED,

SMITHFIELD IRONWORKS, LEEDS, AND SURREY WORKS, BLACKFRIARS ROAD, LONDON, S.E.,

HORTICULTURAL ENGINEERS to HER MAJESTY THE QUEEN, call Special Attention to their

PATENT WROUGHT-IRON MUNICIPAL OR ANGULAR CHAMBERED AND TUBULAR HOT-WATER BOILERS,

And others with **SHELVES**, and Hollow or Ordinary Cast-iron **GRATE BARS**.

SADDLE BOILERS. With WATERWAY BACKS and WELDED BOILERS, any of which are specially adapted for Heating Greenhouses, Conservatories, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c. They are the neatest, cheapest, most effective, and durable of any extant. The MUNICIPAL and TUBULAR ones are remarkable for their great heating power, slow combustion, and the length of time the fire will burn without requiring attention.

These Patterns secured the **FIRST and HIGHEST PRIZE a SILVER MEDAL**, at the Royal Horticultural Society's Exhibition, South Kensington, London, June 1, 1881.

The longitudinal section gives a view of the fire-box, water space, flues, &c. The cross section gives a view of the fire-box, water space and V-shaped back. The front elevation shows it set in brickwork, which is necessary for this class of boiler.

TESTIMONIALS.

Messrs. THOS. GREEN AND SON, LTD., NORTH STREET, LEEDS. Re HEATING APPARATUS. Borough Engineer's Office, Municipal Buildings, Leeds, January 9, 1886. GENTLEMEN,—I have great pleasure in hearing testimony to the efficiency and satisfactory working of the Hot-water Heating Apparatus you erected in these public buildings. The buildings are four storeys high, and we have a total length of about 28,000 feet of piping in them, varying in size from 1½ in. to 6 in. diameter, with their connections, &c. The several offices and rooms can all be in operation at one time or separately, and the heat regulated by means of the valves to the temperature required, even in the coldest weather. Two of your Patent Municipal Pattern Boilers, No. 4, work the whole of this piping easily, although we have three of them fixed. They are very powerful and economical in the consumption of fuel, and I am pleased to be able to report of them and the apparatus so favourably. I am, Gentlemen, yours truly, THOS. HEWSON, Borough Engineer.

Morley House, Bagot, St. Saviour's, Jersey, November 10th, 1886. GENTLEMEN,—The large Municipal Boiler which you sent me last year is doing its work satisfactorily; it is heating 5,000 feet of 4-inch pipe in one of my vineries, and I am quite sure that it has power to work a much greater length, while in cost of fuel it compares favourably with my other Boilers. I have now five of your Boilers in use, and I cannot speak too well of their heating powers, or their comparatively small consumption of fuel. Yours faithfully, (Signed) G. W. BASHFORD.

Messrs., THOS GREEN AND SON, LTD., LEEDS.

"MYTICUTTAH"

(REGISTERED).

PATENTED IN GREAT BRITAIN, FRANCE and GERMANY.

As the S. M. Co.'s "Standard" Tree Pruner is admitted to be the best Pruner for work a distance from the ground, so will the two "MYTICUTTAHS" prove the handiest and most powerful for Pruning and Trimming close to the ground, such as the removal of shoots from roots of trees; also Shrubs, Fruit and Flower Bushes, Vines, and other climbing plants, &c. Their construction enables prickly Shrubs and Bushes to be Pruned without lacerating the hands or wrists, even if gloves are not worn. They will with ease cut the hardest wood growing without injuring the part left by splitting and drawing the sap several inches up and causing decay, as other implements are known to do.

For Illustrated PRICE LISTS of above and other NOVELTIES in PRUNING TOOLS, FRUIT and FLOWER GATHERERS, &c., apply to the

STANDARD MANUFACTURING COMPANY,
ST. ALKMUND'S CHURCHYARD, DERBY;

Or to their Agents, the Principal Ironmongers and Seedsmen at home and abroad.

Must be able to Grow Ferns, double Primulas, Cinerarias, and Bulbs; force Cucumbers, &c., and be well up in General Nursery work. Wages to commence about £1. Churchman and non-abstainer. With this might be combined office of Verger (duties light) in a church. Additional remuneration for whole time, good cottage (£10 10s.) rent-free, water laid on; two tons of coal per annum, and other advantages. Member of **C. E. W. M. S.** welcomed. Good character indispensable.—State experience, qualifications, and give reference to **E. C. U.**, *Gardeners' Chronicle* Office, 41, Wellington Street, Strand, W.C. Only those accustomed to Grow for Market need apply.

WANTED IMMEDIATELY, as **PROPAGATOR**, a young Man experienced in the Propagation of Hardy and Half-hardy Florists' Flowers, and to have charge of Hotheuses.—State wages expected to **M. CUTHBERTSON**, Florist and Seedsman, Rothesay, N.B.

WANTED, a young **MAN**, to **ASSIST** in the Houses, and at Market Stall. A knowledge of Seeds preferred.—**C. WHITING**, Seedsman and Florist, Hereford.

WANTED, **FLORAL APPRENTICES** to the General Market Nursery Business on the 3, 5, or 7 years' system.—Terms and particulars to **FLETCHER, SON AND CO.**, Nurserymen, Seedsmen, and Florists, Chesterfield.

VACANCY for **Garden BOY** of 16, in a good establishment. Only to those who can be well recommended, and who intend to follow up Gardening. Lodgings in Bothy.—**E. BAYMAN**, Holmbury, Dorking.

Propagator Wanted (Indoor).

WANTED, a steady and industrious Man as **PROPAGATOR** in the Houses, and occasionally to act as Salesman. Must be a successful Grower of Clematis, Pot Roses, and Soft-wooded Stuff.—Apply, stating age, where last employed, wages expected, &c., to **JNO. JEFFERIES** and **SONS**, Cirencester.

WANTED, as **FLORIST**, a Man who must be well up in Wreaths, Crosses, Sprays, Bouquets, &c.—Only men of experience and taste need apply, stating full particulars to **POPE AND SON**, King's Norton Nursery, Birmingham.

WANTED, a **JOURNEYMAN**, in a Nursery, with a good knowledge of Fruit Growing, Plants, &c., under Glass. State particulars, with wages.—**W. WATSON**, Polegate Gardens, Sussex.

WANTED, a quick active **MAN** to **Graft**, Grow Roses and Cut Flowers in a small Nursery for Market. State experience, wages expected, &c., to **MR. MORLE**, 1 and 2, Fenchurch Street, E.C.

WANT PLACES.

NOTICE TO ADVERTISERS.—In many instances Remittances in Payment of Repeat Advertisements are received without name, address, or anything beyond the postmark on envelope by which to identify the sender; this in all cases causes a very great deal of trouble, and frequently the sender cannot be identified at all.

Advertisers are requested when Remitting to give their Names and Addresses, and also a Reference to the Advertisement which they wish repeated.

Letters addressed "Poste Restante" to initials or to fictitious names are not forwarded, but are at once returned to the writers.

POSTAL ORDERS.—To Advertisers, Subscribers, and Others.—It is very important in Remitting by Postal Order that it should be filled in payable to **No. 42, DRURY LANE, to W. RICHARDS**, as, unless the number of a Postal Order is known, and it has been made payable at a particular office, and to a particular person, it is impossible to prevent any person into whose hands it may fall from negotiating it.

N.B.—The best and safest means of Remitting is by **POST-OFFICE ORDER**.

E. P. DIXON AND SONS, Hull, can **RECOMMEND** a few competent **HEAD GARDENERS, FOREMEN, and JOURNEYMEN**, and will be glad to give full particulars to any Lady or Gentleman requiring the same.

SCOTCH GARDENERS.

—**JOHN DOWNIE** (of the late firm of Downie & Laird), Seedsman, 144, Princes Street, Edinburgh, has at present on his List a number of **SCOTCH GARDENERS**, waiting engagements. He will be pleased to supply full particulars to any Lady, Nobleman, or Gentleman requiring a trustworthy and competent Gardener.

Gardeners, Bailiffs, &c.

JOHN LAING AND SONS, having filled many important places, can **RECOMMEND** with very confidence, energetic and practical **MEN** of tested ability, and first-rate character. Ladies and Gentlemen in want of Gardeners and Bailiffs, or Gardeners for first-rate Establishments, or Single-handed situations, can be suited, and have full particulars by applying to us. No fees charged.—**JOHN LAING AND SONS**, The Nurseries, Forest Hill, S.E.

RICHARD SMITH AND CO. beg to announce that they are constantly receiving applications from Gardeners, seeking situations, and that they will be able to supply any Lady or Gentleman with particulars, &c.—**St. John's Nurseries**, Worcester.

GARDENER (HEAD); age 35, Scotch.—**J. McPHAIL**, for the last ten years Head Gardener to Colonel Cooper, at Markze Castle, Callooney, will shortly be disengaged. Highest testimonials, and Col. Cooper kindly allows reference.

GARDENER (HEAD), where two or three are kept; age 29, single.—**J. AMYS**, Gardener to the Hon. Mrs. Eliot York, Hamble Cliff, Southampton, can with confidence recommend his Foreman (**G. Dovey**) as above. Disengaged by the end of March.

GARDENER (HEAD).—Married, no family; thoroughly practical man. Used to Management of Large Gardens, extensive Houses, and Large Staff of Men. Can be highly recommended.—**W. T.**, Failand Hill, near Clifton, Bristol.

GARDENER (HEAD); no incumbrance.—**MR. W. BISHOP**, late Gardener to the late Sir E. Jodrell, Bart., and many years at Blygh Park, will be pleased to treat with any Lady or Gentleman requiring the services of a first-class all-round Gardener.—**HEAD GARDENER**, The Grove, Teddington; or, **Head Gardener**, Wesley Hall, Bury St. Edmunds.

GARDENER (HEAD), to any Lady, Nobleman, or Gentleman requiring the services of a thoroughly practical man.—Age 50, married, no incumbrance; first-class character and testimonials. Disengaged March 15. Leaving entirely owing to an alteration in the establishment. Distance no object.—Please address **Park Wern**, Sketty, Swansea, S. Wales.

GARDENER (HEAD); age 33, married, no family.—**W. J. IRELAND**, late of Nostell Priory, and previously with the Marquis of Headfort, is open for re-engagement. Thoroughly conversant with all matters relative to Horticulture. Protestant. Strong and healthy, and not afraid of exerting himself. Left at own request. Testimonials of the highest order for character and ability.—24, Cambridge Street, Eccleston Square, London, S.W.

GARDENER (HEAD); age 28, married.—**MR. THOMAS**, Head Gardener to T. T. Drake, Esq., Shardeloes, Amersham, would be pleased to recommend his late Foreman to any Lady or Gentleman requiring a good all-round gardener; four years in last place; with good reference.—**H.
